SUMMARY To investigate the effect of increasing gestational and postnatal age on the relation between transcutaneous oxygen tension (tcPO₂) and arterial oxygen tension (PaO₂) 160 simultaneous measurements of tcPO₂ and PaO₂ tensions were made on 42 infants born at 24–41 weeks' gestation and aged 0–32 weeks from birth. Irrespective of gestational age a progressive fall in the tcPO₂:PaO₂ ratio with increasing postnatal age was found. At all postnatal ages tcPO₂:PaO₂ tended to be lower in the more mature infants.

Transcutaneous oxygen (tcPO₂) electrodes have been shown to estimate accurately arterial oxygen (PaO₂) in infants in the first week of life, provided that the infant is not severely ill and that perfusion of the skin is adequate.1–3 Few studies of older infants have been performed, but there is some evidence to suggest that tcPO₂ electrodes underestimate PaO₂ in those with bronchopulmonary dysplasia.4 We investigated whether there were any systematic changes in the relation between tcPO₂ and PaO₂ with increasing gestational and postnatal age.

Methods

Infants studied. Simultaneous measurements of tcPO₂ and PaO₂ were made on 160 occasions on 42 infants being treated in the Neonatal Unit of University College Hospital. The median number of observations in each infant was three (range 1–17). The infant was born at 24–41 weeks' gestation, weighing 560–4075 g; 16 were girls and 26 were boys. The Table gives the principal diagnoses.

Thirty three infants survived and nine died. Ninety two observations were made on infants who were breathing spontaneously, eight on infants being treated by continuous positive airway pressure, and 60 on those who were mechanically ventilated. The median fractional inspired oxygen tension (FiO₂) when observations were made was 0.35 (range 0.21–1.00, n=151); on nine occasions when low-flow oxygen was being administered through nasal catheters FiO₂ was not known.

Procedure. Whenever possible, observations were made on the first day of life and then at weekly intervals until the infant was discharged or blood gas analysis was no longer clinically warranted. Observations were omitted if the infants were extremely ill or hypotensive, the peripheral perfusion was poor, as judged visually or by a rectal-toe temperature difference of 6°C or more, or the arterial packed cell volume was less than 30%, as these circumstances may cause underestimation of PaO₂ by tcPO₂.3

Measurement of tcPO₂. A Dräger Transoxode electrode (Drägerwerk, Lubeck, W Germany) was used for measurement of tcPO₂. The membrane material, 25 μm thick Teflon, and the electrolyte were

supplied by the manufacturer. The electrode was heated to 44°C and calibrated with two certified dry gas mixtures containing 0% oxygen (with 10% carbon dioxide and nitrogen) and 12% oxygen (with 5% carbon dioxide and nitrogen). An appropriate allowance for barometric pressure was made. The electrode was attached with an adhesive ring to an area of skin supplied by the artery chosen for measurement of PaO2. A continuous record of tcPO2 was displayed on a chart recorder.

Measurement of PaO2. Whenever possible, samples for measurement of PaO2 were taken from catheters sited in the umbilical artery (n=19) or in peripheral arteries (n=4). When no arterial catheter was available, the sample was obtained by direct puncture either of the right radial or brachial artery (n=109) or of the left brachial or radial artery or a posterior tibial artery (n=28). A 25 gauge 'buttefly' needle was used, with all but 5 mm of the attached plastic tubing removed. For collection of the sample (0.2 ml), two 105 mm long, dry heparinised glass capillary tubes joined together by 5 mm of plastic tubing were used, with one free end connected to the needle. When the artery was punctured, blood rose freely and rapidly into the tubes. The tcPO2 value taken for comparison with PaO2 was recorded 40 seconds after the midpoint of the blood flow to allow for the response time of the tcPO2 electrode. PaO2 was measured at 37°C using an Instrumentation Laboratories 1303 blood gas analyser, the accuracy of which had been checked with tonometered blood. Observations were discarded if the infant was more than minimally disturbed by the sampling procedure or the tcPO2 record showed any pronounced change. To verify that little change occurred the mean difference between the recorded tcPO2 value and tcPO2 value 10 seconds earlier was documented and found to be 0.14 (SD 0.17) kPa; the difference 10 seconds later was 0.15 (0.18) kPa. Mean (SD) rectal temperature at the time of sampling was 37.0 (0.4)°C.

Results

Figure 1 shows the relation between tcPO2 and PaO2 for all the pairs of observations made in the study. Data for infants less than 8 weeks old are given in Figure 1 (a) and for those aged 8 weeks or more in Figure 1 (b). The ratio tcPO2:PaO2 was calculated for each pair of observations, and the relation between this ratio and increasing postnatal age is shown in Figure 2. In both Figures 1 and 2 different symbols are used to indicate data for infants born at less than 30 weeks' gestation or at 30 weeks and above. Figure 3 shows the relation

between tcPO₂:PaO₂ ratio and increasing postnatal age in infants grouped according to gestational age at birth.

Discussion

Inspection of Figure 1 (a) shows that the data points are clustered around the line of identity, and therefore that in infants less than 8 weeks old measurement of tcPO₂ generally gave a good estimate of PaO₂, irrespective of what gestation the baby had been born at. This is confirmed in Figure 2, which shows that the tcPO₂:PaO₂ ratio was usually close to 1.0 during the first eight weeks, but it can also be seen that the tcPO₂:PaO₂ ratio fell progressively with increasing postnatal age, leading to an underestimate of PaO₂ by tcPO₂ that is also apparent in Figure 1 (b). If all the data for infants aged 8 weeks and above are taken together, the mean value for tcPO₂:PaO₂ is 0.83 (SD 0.15) (n=72), significantly lower than the mean value for infants aged less than 8 weeks of 1.11 (0.11) (n=88, p<0.001). In infants who were more than 3 months old, tcPO₂ was almost always below 1.0 and often as low as 0.75 (Figure 2). Clearly, a fall in the tcPO₂:PaO₂ ratio occurred with increasing postnatal age to a level where PaO₂ was substantially underestimated. How much of this effect was due to differences in the skin associated with the different gestational ages of the infants at birth is difficult to assess. The data in Figures 1 (b) and 2 suggest that tcPO₂:PaO₂ was lower in infants born at 30 weeks or above than in less mature infants, and Figure 3 illustrates the trend towards lower values with increasing gestational age: however, no significant effect of gestational age at birth could be shown from these data.

The reasons for the fall in tcPO₂:PaO₂ with increasing postnatal age are not clear and are probably multifactorial. That the effect was not merely due to increasing maturation of the skin was shown by relating tcPO₂:PaO₂ to gestational age plus postnatal age: a much less clear relation emerged than with postnatal age alone (data not shown). Changes in the texture and thickness of the skin and in the capillary bed occur with increasing postnatal age, and permeability to oxygen decreases. All these factors could affect tcPO₂:PaO₂. A further possibility is that the fall in tcPO₂:PaO₂ may sometimes have been related to the presence of chronic lung disease. We could not, however, show such an effect, as six infants more than 8 weeks old had only minor pulmonary problems, yet their data were similar to those for the 13 infants whose lungs were more severely compromised.

Our evidence that tcPO₂ underestimates PaO₂ progressively with increasing postnatal age has several implications. Firstly, infants may be nursed in an unnecessarily high ambient oxygen concentration. As the underestimate of PaO₂ by tcPO₂ only became pronounced in infants more than 3 months old, we doubt if the eyes of preterm infants would thereby be put at increased risk of retrolental fibroplasia, though this remains a remote possibility in the least mature infants. It is probable, though, that treatment with oxygen could be continued for longer than necessary, thus needlessly prolonging stay in hospital. This conclusion re-emphasises the importance of checking tcPO₂ values against PaO₂ measured in carefully taken arterial samples. Our data also imply that the results of studies of older infants, where tcPO₂ is regarded as giving an accurate estimate of PaO₂, should be viewed with caution.

We thank Mr D T Delpy, Mr C Hemsley, and the staff of the Neonatal Unit for their help. This study was supported by the Medical Research Council.
