Diversity in regulation of adhesion molecules (Mac-1 and L-selectin) in monocytes and neutrophils from neonates and adults

C Török, J Lundahl, J Hed, H Lagercrantz

Abstract
The surface expression and regulation of the adhesion promoting glycoproteins Mac-1 and L-selectin was measured on monocytes and neutrophils from neonates and adults. A significant decrease in Mac-1 up regulation on both monocytes and neutrophils was found in neonates after both high ($10^{-7}$M) and low ($10^{-9}$M) concentrations of the chemotactic factor N-formyl-methionyl-phenylalanine (FMLP). A significant difference was obtained after incubation for five minutes, which was further enhanced after incubation for 15 minutes. Factors related to bacterial infections, lipopolysaccharides, activated IgG, and aggregated IgG induced an impaired Mac-1 up regulation on both monocytes and neutrophils from neonates compared with adults. The expression of L-selectin was significantly lower on neutrophils from neonates and was less down regulated upon stimulation with a low concentration ($10^{-12}$M) of FMLP. On monocytes from neonates, the expression and down regulation of L-selectin did not differ from monocytes from adults. Mode of delivery did not influence the regulation of Mac-1 and L-selectin in neonates.

Diversity in expression and regulation of Mac-1 and L-selectin on monocytes and neutrophils may contribute to the increased susceptibility to infections observed in neonates.

(Arch Dis Child 1993; 68: 561–565)

The immunological host defence is immature in the human neonate, which may contribute to the high incidence of overwhelming sepsis in preterm and term infants. The most consistent defect described is the inability of the neonatal neutrophils to accumulate at the site of bacterial invasion. This is partly due to a reduced neutrophil storage pool and a failure to increase the stem cell proliferation rate during sepsis. Previous studies have revealed that neutrophils from neonates have impaired adherence to and migration through endothelium and also impaired chemotaxis.

Immaturity in other defence systems such as decreased opsonic activity can contribute to the increased infection rate. During acute inflammation, neutrophils and monocytes are recruited to the inflammatory site. Neutrophils are important effector cells during bacterial infections and monocytes undergo maturation to inflammatory macrophages performing both immune and non-immune functions.

Both neutrophils and monocytes pass several transient attachments to the vessel walls before the final adhesion to and transmigration through the endothelium. This recruitment is regulated by a sequential interaction of different adhesion molecules. Two important families of adhesion molecules are involved in this recruitment and are designated selectins and integrins. Selectins mediate the first step of attachment to endothelium; this is called 'rolling'. This rolling precedes a firm adhesion that is mediated by the integrin family.

L-Selectin is distributed on most leucocytes and is down regulated upon stimulation with chemotactic factors. Mac-1 is an important adhesion molecule in the integrin family that mediates firm adhesion to endothelium. Upon stimulation with chemotactic factors, Mac-1 is rapidly mobilised to the surface from an intracellular pool. This inverse regulation of L-selectin and Mac-1 is a prerequisite for the sequential interaction between inflammatory cells and endothelium leading to an inflammatory response.

The aim of the present study was to see whether immaturity of expression and regulation of these adhesion molecules on monocytes and neutrophils could predispose to severe infection in the infant.

Methods
Blood samples
Blood was collected from the placental side of the umbilical cord immediately after uncomplicated vagina deliveries ($n=19$) and caesarean section ($n=6$). All infants were full term (37–42 weeks) with a mean birth weight of 3600 g; girls/boys 16/9; and average Apgar scores were 9, 10, 10 at 1, 5, and 10 minutes respectively. For the control samples, blood was collected from healthy non-allergic blood donors aged between 18 and 65 years.

All samples were collected in ethylenediaminetetra-acetic acid (EDTA) tubes and were analysed within four hours.

Leucocyte preparation
EDTA blood was haemolysed in 50 μl aliquots by dilution in 2 ml cold ammonium chloride-EDTA 'lysing reagent' (Ortho Diagnostic Systems) for five minutes at 15°C followed by centrifugation for five minutes at 300 g at 4°C. The leucocyte pellets were washed once in...
0.15 M cold phosphate buffered saline supplemented with 0.1 mM EDTA and 0.02% sodium azide (PBS-EDTA) and were then resuspended in Roswell Park Memorial Institute (RPMI) 1640 medium (Northumbria Biologicals Ltd).

VIABILITY TESTING
Viability testing was performed by incubating leucocyte pellets with carboxyfluorescein diacetate (CFDA) (10 μg/ml) (Becton and Dickinson ImmunoCytometry Systems) for 15 minutes at 18°C followed by one wash in PBS-EDTA at 4°C. CFDA was retained and hydrolysed by intracellular esterases, yielding green fluoresceins. The fluorescence intensity was analysed with flow cytometry (see below) and results are expressed as percent CFDA positive cells.

REAGENTS FOR RECEPTOR MOBILISATION
Lipopolysaccharides prepared from Escherichia coli O26:B6 was used at a concentration of 100 μg/ml. As the effect of lipopolysaccharides on Mac-1 mobilisation is enhanced in the presence of lipopolysaccharide binding protein,26 RPMI was supplemented with 10% heat inactivated normal human sera from healthy AB Rh+ blood donors. N-formyl-methionyl-phenylalanine (FMLP) was diluted to different concentrations from a 10⁻³ M pool stored at −70°C. Lipopolysaccharides and FMLP were purchased from Sigma Chemical. Aggregated IgG was prepared from Gammaglobulin Kabi 165 mg/ml (Kabi Vitrum). The gammaglobulin was diluted to 20 mg/ml in RPMI medium and incubated at 63°C for 30 minutes. After incubation the gammaglobulin was diluted to a final concentration of 2.5 mg/ml. Sera from healthy AB Rh+ blood donor was incubated with heat killed yeast particles to obtain complement activation products, which major chemoattractant is generally considered to be C5a des arg. This sera was then diluted in RPMI medium to a final concentration of 10% and was designated normal human serum in this study.

IMMUNOSTAINING AND FLOW CYTOMETRY
Mac-1 and L-selectin expression on leucocytes was analysed by adding 10 μl of phycoerythrin-conjugated monoclonal anti-CD16 and 10 μl FITC-conjugated anti-Leu 8 respectively (Becton and Dickinson ImmunoCytometry Systems) to the leucocyte pellets prepared as described above. The suspensions were incubated on ice for 30 minutes and then washed twice in cold PBS-EDTA. Isotype matched control antibodies, phycoerythrin-conjugated IgG₂ and fluorescein isothiocyanate (FITC)-conjugated IgG₂ (Becton and Dickinson ImmunoCytometry Systems) were used to define the cut off for positive fluorescence, which was the 99th centile of the distribution of the cells labelled with control antibody. The cells were finally resuspended in 0.5 ml PBS-EDTA and analysed in Epics Profile 1 (Coulter Inc). Based on light scattering properties, each cell is represented by a point in a rectangular coordinate system. Discrimination frames were placed around the granulocyte and monocyte clusters. In control experiments the purity of neutrophils and monocytes within the respective cluster was defined with CD16 monoclonal antibody (Becton and Dickinson ImmunoCytometry Systems) and CD14 monoclonal antibody (Coulter Inc), respectively. The instrument gives the mean fluorescence intensity of the cell population within each discrimination frame.

STATISTICAL ANALYSIS
Results are expressed as mean (SD). Differences between groups were analysed using non-parametric method (Mann-Whitney U test) and were considered statistically significant at p<0.05.

Results
VIABILITY AND CELL PURITY
The viability, measured as percentage CFDA positive cells, was >97% for both granulocytes (neonates 99.1 (0.90%), adults 98.6 (0.9%) and for monocytes (neonates 97.3 (1.2%), adults 98.8 (0.9%). The purity of neutrophils and monocytes in respective clusters was measured with anti-CD16 and anti-CD14 respectively. CD16 positive cells were 97.5 (0.7%) for neonates and 96.7 (1.0%) for adults. CD14 positive cells were 95.1 (2.2%) for neonates and 93.9 (1.3%) for adults.

EXPRESSION OF MAC-1 AND L-SELECTIN ON UNSTIMULATED NEUTROPHILS AND MONOCYTES
The surface expression of Mac-1 on unstimulated (kept at 4°C) monocytes was lower in neonates compared with adults (13.7 (6.3) and 20.6 (9.8) mean fluorescence intensity respectively, p<0.05). On neutrophils, the expression was comparable between neonates and adults (14.9 (6.9) and 12.9 (7.1) mean fluorescence intensity respectively; (table). The expression of L-selectin was significantly (p<0.001) lower on neutrophils from neonates compared with adults but was similar on monocytes (table).

EFFECT OF DIFFERENT INCUBATION TIME AND FMLP CONCENTRATIONS ON MAC-1 MOBILISATION ON NEUTROPHILS AND MONOCYTES
Leucocytes were incubated with buffer alone or buffer supplemented with different concentrations of FMLP at 37°C for five and 15

minutes to obtain mobilisation of Mac-1. We observed a dose and time related increase in Mac-1 expression on monocytes and neutrophils from neonates and adults. The surface expression of Mac-1 on monocytes from neonates was significantly (p<0-05) lower after five minutes incubation with buffer supplemented with FMLP (10^-8 M to 10^-7 M fig 1A). After 15 minutes incubation, monocytes from neonates expressed significantly (p<0-05) less Mac-1 and also after incubation with buffer alone and buffer supplemented with a low (10^-9 M) concentration of FMLP (fig 1B).

The mobilisation of Mac-1 on neutrophils showed a similar pattern as monocytes with significantly (p<0-01) lower surface expression of Mac-1 on neonatal compared with adult neutrophils after incubation for five minutes with buffer supplemented with FMLP (10^-8 M to 10^-7 M; fig 1C). After 15 minutes incubation, neutrophils from neonates expressed less Mac-1 compared with adult neutrophils after incubation with a broader range of FMLP concentrations (10^-9 M to 10^-7 M; fig 1D).

Figure 1 Leucocytes from neonates and adults were incubated with buffer alone or buffer supplemented with different concentrations of FMLP for five (A) and (C) and 15 (B) and (D) minutes at 37°C. After incubation the leucocytes were analysed according to Mac-1 surface expression. The monocyte (A) and (B) and neutrophil (C) and (D) population was gated and analysed by flow cytometry. Results are expressed as mean (SD) and are based on seven experiments; * = p<0-05, ** = p<0-01.

THE EFFECT OF LIPOPOLYSACCHARIDES AGGREGATED IgG, AND C5a ON MAC-1 MOBILISATION ON NEUTROPHILS AND MONOCYTES

To evaluate the effect of factors related to bacterial infections, leucocytes were incubated with aggregated IgG (2-5 mg/ml), normal human serum (10%) and lipopolysaccharides (100 μg/ml) at 37°C for 15 minutes. All these stimuli caused a significantly (p<0-01) lower Mac-1 surface expression on monocytes (fig 2A) and neutrophils (fig 2B) from neonates compared with monocytes and neutrophils from adults.

TIME COURSE OF THE FMLP INDUCED DOWN REGULATION OF L-SELECTIN

Leucocytes were incubated with buffer supplemented with FMLP 10^-12 M at 37°C for 1-5 minutes. During this incubation, surface expression of L-selectin decreased on neutrophils from both adults and neonates but the decrease was significantly (p<0-05–p<0-001) less pronounced on neonates after 2-5 minutes of incubation (fig 3B). Even if neonatal neutrophils expressed less L-selectin when kept at 4°C compared with adults, surface expression after five minutes incubation with FMLP (10^-12 M) at 37°C was significantly (p<0-05) higher on neonatal neutrophils (8-8 (1-7) vs 6-4 (3-3) mean fluorescence intensity). On monocytes, the down regulation was less pronounced compared with neutrophils and did not differ between neonates and adults (fig 3A).

COMPARISON OF MAC-1 AND L-SELECTIN EXPRESSION FROM NEONATES DELIVERED VAGINALLY VERSUS NEONATES DELIVERED BY CAESAREAN SECTION

Samples from six neonates delivered by caesarean section were compared with samples drawn from six neonates vaginally delivered to
evaluate the influence of mode of delivery for expression of Mac-1 and L-selectin. The expression of Mac-1 on monocytes and neutrophils kept at 4°C and after stimulation with FMLP (10^{-7} M) at 37°C for 15 minutes did not significantly (p>0.8) differ between the two groups. Additionally, surface expression on monocytes and neutrophils kept at 4°C and the FMLP (10^{-12} M) induced down regulation of L-selectin were not significantly (p>0.8) influenced by mode of delivery in our subjects (data not shown).

Discussion

Recruitment of inflammatory cells is a key event in host defence against microbes and involves adhesion to and migration through the endothelium of the circulating inflammatory cells.15-17 Neutrophils appear within hours after onset of inflammation followed by monocytes and lymphocytes which accumulate after 6-8 hours.19 The mechanisms for this sequential accumulation are not fully known but differences in expression and regulation of adhesion molecules is probably of importance.

In this study we demonstrate a dose and time related impaired mobilisation of Mac-1 on neonatal monocytes compared with adults after incubation with the chemotactic factor FMLP. This impaired mobilisation was observed also after stimulation with other factors related to bacterial infections such as lipopolysaccharides, aggregated IgG and C5a, indicating a stimuli independent phenomenon. Neutrophils from neonates showed an impaired Mac-1 mobilisation which confirms other studies demonstrating a impaired Mac-1 mobilisation on neonatal neutrophils compared with adults after stimulation with FMLP and C5a.27-29 despite a quantitative similar pool of Mac-1.30

It is not clear whether impaired Mac-1 expression accounts for the predisposition to infection in neonates as heterozygotes for congenital deficiency of Mac-1 have no increased susceptibility to infections31; furthermore only a minor part of the total pool of Mac-1 is sufficient for binding and uptake of C3bi coated particles.32

We did not find any differences in the expression and down regulation of L-selectin on monocytes between neonates and adults. This resemblance to adults suggests that the recruitment of monocytes is less affected in neonates as it has been proposed that L-selectin mediates a major part of monocyte adhesion to activated endothelium under non-static conditions.33

We observed a decreased surface expression of L-selectin on neonatal neutrophils and an impaired down regulation upon stimulation with low concentrations of FMLP. On neutrophils, the surface level of L-selectin seems to be
related to the adhesion properties to endothelium under conditions of shear stress, during which CD18 dependent adhesion is reduced. The reduced surface level of L-selectin may contribute to the impaired CD18 independent adhesion of neonatal neutrophils to endothelium, as discussed by others.

In our studies, we did not find any influence of mode of delivery on Mac-1 and L-selectin regulation, confirming other studies on Mac-1 regulation. We have demonstrated diversity in the inverse regulation of Mac-1 and L-selectin on both monocytes and neutrophils in neonates. This may reflect 'immaturity' in neonatal monocytes and neutrophils, which together with 'immaturity' in other defence systems probably contribute to the increased susceptibility to infections.
