The mental health of refugee children

M Fazel, A Stein

The UK is facing a major increase in the number of people seeking asylum each year, of whom approximately a quarter are children. The stressors to which refugees are exposed are described in three stages: (1) while in their country of origin; (2) during their flight to safety; and (3) when having to settle in a country of refuge. The evidence concerning the impact of displacement on children’s mental health is reviewed and a framework for conceptualising the risk factors is proposed. The available literature shows consistently increased levels of psychological morbidity among refugee children, especially post-traumatic stress disorder, depression, and anxiety disorders. The principles underlying the delivery of mental health care for these children are also considered. It is argued that much primary prevention can be undertaken in the school context. Some key aspects of British immigration law are examined and the tension between the law and the best interests of the child principle is discussed. There is particular concern for the plight of unaccompanied children. Attention to the mental health needs of this vulnerable group is urgently required.

One per cent of the world’s population, 50 million people, are currently uprooted—23 million are refugees who have sought safety in another country, and 27 million are displaced within their own country. In the past decade the worldwide refugee population has increased tenfold and all indicators show that this number will continue to rise. (A refugee is defined as: a person who, “owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable or, owing to such fear, is unwilling to avail himself of the protection of that country; or who, not having a nationality and being outside the country of his former habitual residence as a result of such events, is unable or, owing to such fear is unwilling to return to it”. (1) The UK is facing a major increase in the number of people seeking asylum, with 100 000 applications made in the year 2000, representing a 250% increase in just four years. (2) The journey to a country of refuge can also be a time of further stress. It can take many months and expose the refugees to more life threatening dangers. Refugee children at these times can experience separation from parents, either by accident or as a strategy to ensure their safety. As international immigration controls tighten, more children are being placed in the hands of smugglers to ensure their escape, either as the only representative their family can afford to send away or in the hope that the child alone would have better chances of gaining refugee status. (3) The final stage of finding respite in another country can be a time of additional difficulty as many have to prove their asylum claims and also try to integrate in a new society. This period is being increasingly referred to as a period of “secondary trauma” to highlight the problems encountered. On arriving, a refugee child will need to settle into a new

The mental health of refugee children

Table 1  Risk factors for mental health problems in refugee children

| Parental factors | Post-traumatic stress disorder (PTSD) in either parent
| Torture, especially in mother
| Death of or separation from parents
| Direct observation of the helplessness of parents
| Underestimation of stress levels in children by parents
| Unemployment of parents
| Child factors | Number of traumatic events—either experienced or witnessed
| Expressive language difficulties
| PTSD leading to long term vulnerability in stressful situations
| Physical health problems from either trauma or malnutrition
| Older age
| Environmental factors | Number of transitions
| Poverty
| Time taken for immigration status to be determined
| Cultural isolation
| Period of time in a refugee camp
| Time in host country (risk possibly increases with time)

| School and find a peer group. Children might have to prematurely assume adult roles; for example, as a vital language link with the outside world.

PSYCHOLOGICAL IMPLICATIONS OF DISPLACEMENT FOR CHILDREN

There is considerable evidence that refugee children are at significant risk of developing psychological disturbance as they are subject to a number of risk factors. Table 1 provides a framework for conceptualising these risk factors. Refugee children suffer both from the effects of coming from a war zone and of adjusting to an unfamiliar culture. These stressors also affect their families. Moreover, consistent research findings show that as the number of risk factors accumulates for children, the likelihood that they will develop psychological disturbance dramatically increases. In particular, Rutter has shown the synergistic effects of multiple risk factors on adverse child outcome.

Studies of children in exile show that the prevalence of emotional and behavioural disorders is high, with the most frequent diagnostic categories being post-traumatic stress disorder (PTSD), anxiety with sleep disorders, and depression. The incidence of these disorders is difficult to estimate but findings show that as the number of risk factors accumulates for children, the likelihood that they will develop psychological disturbance dramatically increases. In particular, Rutter has shown the synergistic effects of multiple risk factors on adverse child outcome.

Children, however, often present with a mixture of the symptoms listed and not necessarily fulfilling a single diagnostic category, for example with a mixture of post-traumatic and depressive symptomatology.

Cambodian refugees are the most widely studied group; in a study of 46 children followed up over a number of years, 47% had an Axis 1 diagnosis and comorbidity was common. In particular this study found rates of PTSD at 40%, depression at 21%, and anxiety at 10%. Three years later, levels were still high, with 48% manifesting PTSD and 41% depression. After six years, PTSD was still prominent and a strong relation was found between PTSD and later stressful events, suggesting that the child is left more vulnerable to later traumatic experiences.

Some studies have attempted to identify protective factors that enable children at high risk to be more resilient. These include: (1) a supportive family milieu; (2) an external societal agency that reinforces a child’s coping efforts; and (3) a positive personality disposition. The response and functioning of a parent during and after stress can also have a profound effect on child behaviour. Brown and Harris found a greater vulnerability to depression in adults who lost a parent in childhood, and that the key predictor of this vulnerability was the quality of care giving the child received after the loss itself.

In addition to the mental health needs of refugee children, there have been studies that have highlighted considerable physical health problems. A study of newly arrived refugee children in New York showed that 30% had conditions that required further medical attention. Another study in Sweden found 15% of refugee children had iron deficiency anaemia.

PRINCIPLES OF MENTAL HEALTH CARE

When planning for the mental health needs of refugee children, two main areas need targeting: firstly, the provision of appropriate help for those experiencing psychological difficulties; and secondly, to pay attention to develop primary preventative strategies to this high risk group.

Traumatic events can have an effect on a child’s emotional, cognitive, and moral development because they influence the child’s self perceptions and expectations of others. However, finding appropriate ways to treat these problems is hampered by the lack of reliable evidence for the effectiveness of clinical therapeutic interventions with refugee children as most of the research has been conducted following single traumatic events (such as floods, single school shootings). Many refugee children, however, have experienced prolonged and repeated trauma.

The general consensus is that there is a need for a variety of different treatments, including individual, family, group, and school based interventions. Cognitive behavioural treatment for single traumatic events has been used, and a number of case series and single case studies have reported good results for treatments including play, art, music therapy, and PTSD telling. Of added significance are the post-traumatic symptoms of parents and the impact of these on their capacity to parent.

Table 2  Summary of common presenting symptoms of psychological disorders in refugee children

| Post-traumatic stress disorder | Persistent avoidance of stimuli: specific fears; fear of being alone; withdrawal
| Re-experiencing aspects of the trauma: nightmares; visual images; feelings of fear and helplessness
| PTSD leading to long term vulnerability in stressful situations
| Depression | Low mood
| Loss of interest or pleasure
| Declining school performance
| Conduct disorders

No studies have evaluated the benefit of group treatments, however, based on evidence for groups in other circumstances, it would appear that this may be a good way to help children develop a sense of coping and mastery and sharing ways of solving common problems. A number of children’s disorders could be addressed directly; for example, many suffer from depression and common sleep problems for which psychotherapeutic treatments and medication are available.

Addressing the treatment needs of refugee children can often seem overwhelming to those involved as they do not easily fit with prescribed care packages and often require working with many different professionals and agencies such as interpreters, legal/immigration teams, voluntary organisations, ethnic support groups, social services, and schools. This unavoidably requires more time and resources. Successful programmes emphasise the role of cross-cultural teams who can work in an extended outreach manner. Some programmes have also tried to integrate traditional healing methods to try and enhance the effectiveness of treatment. Home based or school based work has advantages with families who might have a lingering distrust of authority.

Importance of schools

A vital aspect of care for refugee children is care in primary prevention; schools are uniquely placed to undertake such work. The goals of primary prevention can include enhancing resilient behaviours in children; schools offer an excellent framework for this, as well as monitoring of academic progress, and behavioural and social adaptation. Schools provide a place to learn, facilitate the development of peer relationships, and help provide a sense of identity. In particular, for refugee children, schools can play a vital part in their integration by becoming an anchor, not only for educational but also for social and emotional development, and as an essential link with the local community for children and parents. There is good evidence that a proportion of children at high risk of developing long term psychological sequelae do however become competent young adults. One of the key protective factors in influencing this outcome is the school that acts as a stable social support. This support helps to develop children’s resilience by enhancing their individual competencies, in turn adding to their self worth and sense of control over their environment.

TENSIONS BETWEEN BRITISH IMMIGRATION LAW AND THE BEST INTERESTS PRINCIPLE

The rights of asylum seeking children in the UK are limited. When the UK government ratified the UN Convention on the Rights of the Child in 1991, it entered a reservation in applying this legislation to refugee children “in so far as it relates to the entry into, stay in, and departure from the UK on those who do not have the right under the law of the UK to enter and remain in the UK”. This reservation is one of the rare areas of UK law concerning children where the best interests principle does not play a part or where the protection of the child is not the paramount concern.

The UK ranks ninth among European countries in terms of asylum seekers per head of population. Statistics from the year 2000 show that the largest numbers arriving in the UK were from Iraq, Sri Lanka, the Federal Republic of Yugoslavia, Iran, and Afghanistan. Less than one third of asylum applications were allowed to stay (for example, 11% were granted full refugee status and 23% Exceptional Leave to Remain—a status which is reviewed after five years). Since the influx of refugees into Britain significantly increased following the Balkan conflict there have been four major changes in UK National Immigration law in eight years. The most recent change in the 2001–02 parliamentary session has placed new emphasis on induction centres, accommodation centres, reporting centres, and rapid removals. The policy of dispersing asylum seekers around the country will continue and the number of places in detention centres will increase fourfold.

The thrust of these changes has been to deter non-political refugees from entering Britain. Whether it has achieved this
objective is unclear; however, it is evident that it has made life much “less welcoming” for those who have entered the country. The possible impact of these policies on children can be substantial and needs to be carefully planned (see table 3). For example, the government has stated that it is “committed to removing and the use of dedicated detention facilities”, but how this can be done humanely, especially when children are involved, needs careful consideration. In fact, it may be that such removals may infringe children’s rights.

When considering the impact of the dispersal system on refugee children, this newer government policy may have further aggravated their plight. The aim of this policy is to lift the burden of numbers away from the southeast of England. However, it disrupts the education and stability of children who have been placed in local schools by forcing them to move suddenly or risk losing any rights to future support. School transition is a significant event for any child and can lead to a decline in the perception of support from school; frequent relocation is associated with failing academic achievement and behavioural difficulties.36 42 43

Unaccompanied children

A particularly vulnerable group of refugee children are those who are “unaccompanied” and defined as “separated from both parents and for whose care no person can be found who by law or custom has primary responsibility”.44 45 The numbers of unaccompanied children are rising significantly in Western countries and are estimated to comprise 2–5% of any refugee population. At any one time there may be up to 100 000 separated children in Western Europe alone. Their vulnerabilities are not only because they are bereft of support systems such as family and often community life,36 40 41 but also because they are at increased risk of neglect, sexual assault, and other abuses.37 46 It may, however, be that the kind of children that manage to get to the UK in the face of all the adversity are a relatively resourceful and resilient group.47

The smuggling of children across borders has become a growing international concern. Children can be exposed to potential abuse and exploitation en route or in the country of destination. The children often arrive with false documents or with no papers at all. Many are unwilling or unable to tell their destination. The children often arrive with false documents or potential abuse and exploitation en route or in the country of origin.36 This is further complicated by the myriad changes brought about by migration.36 46

Children as a group have greater dependence on outside sources for their protection and care and have their own specific developmental and emotional needs. However, immigration law in the UK does not appear to have always taken account of the best interests of these children.46 Refugee children are a silent group that are easily overlooked. Attention to the mental health needs of this vulnerable group by government and other policy makers is urgently required.

CONCLUSION

The multidimensional effects of trauma on children and their families are compounded by forced uprooting, multiple losses, and the myriad changes brought about by migration.14 19 Children as a group have greater dependence on outside sources for their protection and care and have their own specific developmental and emotional needs. However, immigration law in the UK does not appear to have always taken account of the best interests of these children.46 Refugee children are a silent group that are easily overlooked. Attention to the mental health needs of this vulnerable group by government and other policy makers is urgently required.

ACKNOWLEDGEMENTS

We are grateful to the charity Action for Children in Conflict for funding our work with refugee children and to Professor Guy Goodwin-Gill for his helpful comments on the manuscript.
