Should parents accompany critically ill children during inter-hospital transport?

J Davies, S M Tibby, I A Murdoch

Background: Parental accommodation during inter-hospital transportation (retrieval) of critically ill children is not commonplace in the United Kingdom.

Methods: A three month pilot of parental accommodation was undertaken in 2002 (143 retrievals), after which time the policy was adopted as standard practice. A follow-up audit was performed in 2004 (136 retrievals).

Results: Findings were remarkably consistent between the two periods. Staff perceived little or no added stress during the majority of transfers (96% in 2002, 98% in 2004), and felt able to perform medical interventions without hindrance (98% in 2002, 100% in 2004). There was good agreement between medical and nursing staff regarding perception of stress and ability to perform interventions (phi statistic 0.57 to 1.00). Adverse events occurred during 11 (3.9%) retrievals; six of these involved a parent exclusively. Stress tended to be associated with adverse events or parental behaviour rather than disease acuity. Staff vetoed the offer of accommodation on 11 occasions, for a variety of reasons. The majority of parents found the experience safe, beneficial, and perceived a reduction in stress as a result. These data may inform other retrieval services who are considering adopting a similar policy.

METHODS

A preliminary, anonymised survey of 100 PICU staff was undertaken in April 2002, to gauge attitudes regarding parental accommodation. Although 72% of respondents supported this concept, one third of this group specified that accommodation should not be offered unconditionally. Several themes were identified, including: severity of the child’s illness, mental state of the parents, a clear explanation of the benefits and risks being given to parents before embarkation, and the ability of the ambulance crew to look after parents if cardiopulmonary resuscitation was needed. Many staff expressed concerns that they would be placed under undue stress, and may be inhibited from carrying out medical procedures.

On the basis of the survey, a three month pilot was undertaken between October and December 2002 (period 1), whereby one parent or guardian was offered the opportunity to travel in the ambulance. Any of the retrieval team members (doctor, nurse, ambulance driver) had right of veto. Parents were given an information sheet about what to expect when travelling in the retrieval ambulance, and retrieval staff discussed aspects of safety with parents prior to departure. Before commencing the pilot, clarification was sought about cover provided by the ambulance service’s insurance policy with respect to parental accommodation.

Data were collected prospectively concerning patient demographics, retrieval team composition, medical and nursing interventions required during the journey (interventions were defined as those over and above routine physiological monitoring), and the occurrence of adverse events. The definition of an adverse event has been published previously. Briefly, an adverse event was defined as any unforeseen occurrence which could actually or potentially affect patient care or the safety of anyone in the ambulance. These included: (a) physiological deteriorations (for example, hypotension, hypoxia); (b) equipment/therapy failures (for example, loss of oxygen supply, mechanical ventilator malfunction); or (c) other (motor vehicle accident, aggressive/abusive behaviour). Nursing and medical staff were
asked independently, via a questionnaire, to rate their stress levels and perceived ability to intervene during the transport. Rating was via a five point Likert scale, ranging from “stress free” to “very stressful”, and from “intervene easily” to “felt inhibited”. Staff were also asked to state whether or not they thought it was beneficial to have a parent accompanying their child.

Parents were given a questionnaire after arriving in the PICU, asking if they had been given the opportunity to travel in the ambulance, and asking about perceived levels of safety and information given during the transfer.

Following the pilot, parental accompaniment was adopted as standard practice, and a follow up audit was undertaken 18 months later, between April and June 2004 (period 2).

Ethical approval was not sought for this audit; however, the audit was registered with our hospital Trust via the standard procedure.

Statistics
Data are presented as raw counts and percentages, while summary statistics are reported as median (interquartile range). Demographic data are compared using the Mann-Whitney test (continuous) and \( \chi^2 \) test (categorical). For the staff questionnaire, inter-observer agreement was assessed using the phi statistic (\( \Phi \)).\(^{17}\) Phi is more robust than kappa in situations where the majority of outcomes cluster at one extreme (for example, if the majority of retrievals were perceived as stressful). When this occurs, kappa derived agreement over and above chance is small, producing very low kappa values. Phi corrects for this phenomenon, producing a chance independent measure of inter-observer agreement.\(^{18}\) Like kappa, values for \( \Phi \) range from -1.0 to +1.0, with level of agreement interpreted as follows: less than 0, poor agreement; 0 to 0.2, slight; 0.2 to 0.4 fair; 0.4 to 0.6 moderate; 0.6 to 0.8 substantial; and 0.8 to 1.0, excellent agreement.

RESULTS
Staff questionnaires were returned for 143/155 (92%) of transfers, and was accepted in 71% (178/250) of these. The commonest reason for declining accompaniment was the desire for both parents to travel together. The team was unable to offer accompaniment due to a parent not being present at the referring hospital on 18/279 episodes (6.5%), and staff veto occurred on 11/279 occasions (3.9%). Reasons for retrieval team veto were varied, and are shown in table 3. Interestingly, the majority of these were not patient related, but rather involved staff or parents, or pertained to a logistic aspect of the retrieval.

Parental accompaniment was offered for the majority (250/279) of transfers, and was accepted in 71% (178/250) of these. The commonest reason for declining accompaniment was the desire for both parents to travel together. The team was unable to offer accompaniment due to a parent not being present at the referring hospital on 18/279 episodes (6.5%), and staff veto occurred on 11/279 occasions (3.9%). Reasons for retrieval team veto were varied, and are shown in table 3. There was no obvious relation between the occurrence of team veto and the seniority of the team members.

The majority of staff found parental accompaniment to be non or minimally stressful (96% period 1, 98% period 2), and found little or no difficulty in performing medical/nursing interventions (98% period 1, 100% period 2). There was generally high agreement between nursing and medical staff.

regarding their perception of stress levels and ease of intervention, which improved between periods 1 and 2 (fig 1). Interestingly, staff stress tended to be influenced more by parental factors than disease severity or level of staff seniority, with some of the highest stress scores reported during retrievals where a parent related adverse event occurred. On these occasions nurses tended to report higher stress scores than doctors. Interestingly, this was not associated with reported difficulty in performing interventions.

The percentages of staff rating the experience as beneficial/non-beneficial/neither were 79/9/12% (medical) and 88/7/5% (nursing).

Parental questionnaire response rates were identical across the two periods, at 37%. Overall, 98% of respondents classified their personal safety in ambulance as very good or excellent, and 85% classified the information provided during and prior to the ambulance journey as very good or excellent. A recurrent theme that emerged was an overall reduction in parental stress as a consequence of accompanying their child; this included one parent who was present while her child required cardiopulmonary resuscitation in the ambulance.

Figure 1  Agreement between medical and nursing staff according to the perception of stress and the ability to intervene while in the ambulance. Phi (Φ) was calculated by converting the above 5×5 tables to 2×2 tables, with scores of 1–2 indicating the absence of stress/difficulty, and scores of 3–5 indicating presence of stress/difficulty. Φ = [(odds ratio agreement)0.5 − 1]/[(odds ratio agreement)0.5 + 1].

DISCUSSION

The results of this audit show that parental accompaniment during paediatric retrieval is feasible, appears beneficial for parents, and generally provides little in the way of stress or hindrance to staff.

It is interesting to note that many of the potential difficulties predicted in our initial staff survey were not realised. One third of PICU staff respondents in the pre-pilot survey who were in favour of parental accompaniment stipulated that a series of conditions should be fulfilled before it is offered. However in practice, staff veto was only taken on 3.9% of occasions, and adverse incidents involving parents reported in 6/178 (3.4%) of accompanied transfers. A similar discrepancy between perceived and actual difficulty has been shown in a large United States survey of 110 retrieval teams.13 Thirty six per cent of teams who do not allow parental accompaniment predict potential problems with this practice; however, difficulties are reported by only 8% of teams who allow accompaniment.13 It has also been shown that parental presence in the accident and emergency setting does not adversely affect clinical performance or increase anxiety among the attending staff.13

ARDS, acute respiratory distress syndrome; DGH, district general hospital.
Although rare, parent-related adverse events during the retrieval did have an impact on our staff, producing a degree of stress that was higher among nurses. Adverse events causing greatest stress were those that involved a parent becoming unwell, or exhibiting aggressive behaviour. Although staff did not perceive difficulty in performing interventions on these occasions, we are unable to assess whether stress compromised performance in other ways (such as decision making and technical competence); thus this factor must be born in mind by other retrieval services that are considering parental accompaniment. Conversely, many staff members reported that having a parent present produced a calming effect on non-ventilated patients, similar to the United States experience. Other benefits reported by staff included opportunities to develop a rapport with the parent, explain aspects of the child’s illness, clarify what to expect while in the intensive care unit, and to take a full medical history.

These themes were mirrored by the parents’ survey, where the perception of benefit was an unambiguous and recurrent qualitative finding. It was remarkable how similar many of the comments were to those reported from an audit in the United States. The latter report highlighted that parental requests for accompaniment were more likely for children who were older, non-ventilated, and for those who have been previously well (as opposed to suffering from chronic illness); conversely, disease acuity did not appear to influence the desire to travel in the ambulance. We also found that parents who did not accompany often reported additional stress associated with negotiating transport to the referral centre.

A service development may initially be followed by a honeymoon phase, after which time enthusiasm for the development wanes, or deficiencies become apparent. Thus, only during medical procedures. Am J Dis Child 1990; 144:270–1.

What is already known on this topic

- Parental accompaniment during inter-hospital transport of critically ill children is uncommon in the UK
- Experience from the United States suggests that this may place extra stress on staff

What this study adds

- Parental accompaniment per se does not appear to increase staff stress nor compromise the performance of medical interventions in the majority of occasions. When present, staff stress tends to be associated with parental behaviour and the occurrence of adverse events rather than the child’s disease acuity
- Although adverse events were rare, a significant proportion involved a parent directly
