Acid suppression does not change respiratory symptoms in children with asthma and gastro-oesophageal reflux disease

K Størdal, G B Johannesdottir, B S Bentsen, P K Knudsen, K C L Carlsen, O Closs, M Handeland, H K Holm, L Sandvik

Background: Epidemiological studies have shown an association between gastro-oesophageal reflux disease (GORD) and asthma, and oesophageal acid perfusion may cause bronchial constriction. However, no causative relation has been proven.

Aim: To assess whether acid suppression would lead to reduced asthma symptoms in children with concomitant asthma and GORD.

Methods: Thirty-eight children (mean age 10.8 years, range 7.2–16.8; 29 males) with asthma and an oesophageal acid reflux index (RI) ≥ 5.0 assessed by 24 hour oesophageal pH monitoring were randomised to 12 weeks of treatment with omeprazole 20 mg daily or placebo. The groups were similar in age, gender, mean reflux index, and asthma severity. Primary endpoints were asthma symptoms (daytime wheeze, symptoms at night, in the morning, and during exercise) and quality of life (PAQLQ). Secondary endpoints were changes in lung function and the use of short-acting bronchodilators. At the end of the study a repeated pH study was performed to confirm the efficacy of acid suppression.

Results: The change in total symptom score did not differ significantly between the omeprazole and the placebo group, and decreased by 1.28 (95% CI 0.29 to 0.70) in the placebo group. Change in lung function and use of short-acting bronchodilators were similar in the groups. The acid suppression was adequate (reflux index < 5.0) under omeprazole treatment.

Conclusion: Omeprazole treatment did not improve asthma symptoms or lung function in children with asthma and GORD.
applied as primary endpoints. The first questionnaire assessed asthma symptoms over the past four weeks (table 1), and the second was the validated Pediatric Asthma Quality of Life Questionnaire (PAQLQ). Lung function was monitored by spirometry (Jaeger, Germany) according to accepted standards at weeks 0, 6, and 12: forced expiratory volume in 1 second expressed as percent of vital capacity (FEV₁%) and forced expiratory flow at 25–75% of lung volume (FEF₂₅–₇₅) were registered. FEF₂₅–₇₅ was chosen to detect changes in resistance in the smaller airways. The use of rescue medication with short acting β₂ agonists during the past two weeks was recorded at weeks 0, 6, and 12. Other asthma medication was not changed unless required due to exacerbations during the study period. If changes in asthma medication occurred, this was recorded to make necessary corrections in the analyses.

Skin prick tests and specific IgE against common airway allergens (household animals, pollen, house dust mite, cladosporium) and food antigens (egg, milk, soy, fish, peanuts) were performed if this had not been done during the last three years. Total IgE in full blood samples together with cell counts were measured at inclusion, and eosinophilic cationic protein (ECP) was measured at weeks 0 and 12. Patients with total IgE above the age specific cut-off level, increased specific IgE, and/or positive skin prick test were classified as atopic asthmatics.

To confirm that adequate acid suppression (reflux index ≥5.0) had been achieved, the consenting participants performed a repeated pH study before the treatment ended.

RESULTS

Of the initial 165 children with asthma and symptoms of GORD who consented to a pH study, 45 (28%) had an RI $>5.0$. Three were not eligible for randomisation because of paucity of asthma symptoms as described previously, two withdrew before randomisation, and two had incomplete pH studies.

The remaining 38 children were randomly allocated to omeprazole or placebo treatment. The groups were similar in age and gender distribution, mean reflux index, and asthma severity (table 2). One in each group withdrew because of suspected side effects (headache, worsened asthma symptoms), leaving 18 in each group for final analysis (fig 1).

The change in mean symptom score and PAQLQ from baseline did not differ significantly between the omeprazole and placebo groups (table 3). Changes in subscores listed in table 2 improved, but with no significant differences between the groups (data not shown). Changes in spirometry values, the use of short acting bronchodilators, and ECP were similar in the two groups (table 3).

The 11 patients with RI $>10.0$ were analysed separately, and an improvement in PAQLQ of 0.96 (95% CI −1.6 to 3.6) in the omeprazole and of 0.34 (95% CI −0.14 to 0.82) in the placebo group was found (p = 0.24). Selecting the more symptomatic asthma patients (baseline PAQLQ $<5.0$, five in each group) showed an improvement in PAQLQ of 0.96 (95% CI −0.08 to 2.00) in the omeprazole group and of 0.50 (95% CI 0.11 to 0.89) in the placebo group (p = 0.29).

Analysing atopic (n = 25) and non-atopic (n = 11) children separately showed similar baseline reflux indexes in the two groups (9.3% vs 9.4%). In the atopic children PAQLQ improved by 0.55 (95% CI 0.24 to 0.85) in the omeprazole group compared to 0.56 (95% CI 0.29 to 0.84) in the placebo group (p = 0.94). In the non-atopic asthma patients PAQLQ improved by 0.76 (95% CI −0.40 to 1.94) in the omeprazole and by 0.32 (95% CI −0.02 to 0.66) in the placebo group (p = 0.34).

The acid suppression by omeprazole was adequate (RI $<5.0$) at a repeated pH study in seven of the eight patients consenting to a second pH study, with a mean reduction in RI of 4.9 (2.7–7.1, p = 0.001). In the placebo group the second pH study was abnormal in five of seven patients.

DISCUSSION

The present study did not show any effect of omeprazole treatment on asthma symptoms or quality of life in children with concomitant asthma and GORD. Nor were there any significant effects of oesophageal acid suppression on lung function and the use of β2 agonists.

Studies on omeprazole in adults with asthma have in accordance with our study failed to prove any effect on asthma outcome,24,25 though some smaller studies report improvement in peak expiratory flow or asthma symptoms.26,27 In children with asthma only one uncontrolled study has been published, reporting on a variety of treatments including proton pump inhibitors.28

Most of the previous studies on acid suppression in asthmatics with GORD have not included measurements of the efficacy of GORD treatment, and thus cannot reliably answer the more complicated question whether reduced oesophageal acid exposure improves lung symptoms. We intended to perform a second pH monitoring in all participants to ensure that adequate acid suppression was achieved. Less than half consented to a second study; thus some of the treated children may have received inadequate treatment for their acid reflux. The dosage of 20 mg omeprazole corresponds to 0.25–1 mg/kg, sufficient for the majority of children with GORD.29 A longer duration of

Acid suppression in asthma and GORD

What is already known on this topic

- Epidemiological studies have repeatedly shown an association between GORD and asthma
- Acid perfusion of the oesophagus may induce bronchoconstriction

What this study adds

- Acid suppression in children with asthma and GORD did not improve asthma symptoms
- Subgroups with the more severe forms of asthma and GORD may benefit from acid suppression of asthma symptoms

Treatment may be required to achieve the potential effect on asthma than in GORD without respiratory symptoms. Considering these limitations, we would have expected at least a trend towards a treatment effect in our study if acid suppression was of clinical importance in asthmatic children with GORD.

Our study was relatively small, but adequately powered to detect significant differences in major efficacy outcomes. The lack of differences in outcome in subgroup analysis in children with atopic versus non-atopic asthma may be due to small sample sizes. Children with more severe reflux disease (RI >10.0%) may have a treatment effect as suggested by the trend in our study, but the sample is too small to draw firm conclusions.

Studies on proton pump inhibitors using impedance measurements have failed to prove any effect on non-acidic reflux. The differentiation between acid and non-acidic reflux regarding respiratory symptoms may be important. The data showing no effect of acid suppression on asthma should therefore not be generalised into treatment of GORD in general; as suggested by some studies, surgical treatment may have an effect.

Most children with GORD have neither histological nor macroscopic signs of oesophagitis, and the risk of oesophagitis in individuals with GORD increases with age. One of the proposed mechanisms for acid exposure to the oesophageal mucosa and bronchoconstriction may be restricted to those having an oesophagitis which exposes the afferent vagal nerve to acid. Our study population did not undergo endoscopy, and thus this question cannot be addressed.

Our study included children and adolescents from 7 years of age; studying younger children may yield different findings. The main problem in the younger age group is the definition of asthma, with a limited access to lung function tests. Children with respiratory symptoms from GORD may have an effect.

A subgroup of patients with a temporal relation between gastrointestinal and respiratory symptoms has been suggested to benefit from acid suppression. However, only a few of the patients in the present study fulfills this criterion. The children studied were mainly well treated asthmatics, as shown in table 2. A treatment effect may have been found if only children with severe asthma had been included. However, the children included in the present study reflect the asthma population, with most of the children with mild or moderate persistent asthma, and relatively well controlled asthma on daily inhaled steroids. Thus improvement in asthma outcome may be difficult to obtain and a possible ceiling effect needs consideration, as suggested by the analysis in the subgroup with most severe asthma and lowest PAQLQ at baseline.

Conclusion

The present study could not show any effect of a 12 week treatment with a proton pump inhibitor on asthma symptoms, quality of life, or lung function in children with asthma and GORD. A causal relation between acid reflux and asthma remains unproven.

ACKNOWLEDGEMENTS

We acknowledge: Aase Urkedal, Laila Aaserud, Jan Ivar Holme, Frode Njå, Tore Roed, and Aud Gaasemyr for recruiting patients to the study; study nurses Ingunn Malmberg and Kari Torp Hansen; Jarle Rugvetein, Knut Dahl-Jørgensen, Knut Olav Bøe; and Morton Pettersen for valuable comments to the study protocol; and the Norwegian Foundation for Health and Rehabilitation and AstraZeneca for financial support.
