1105 OUTCOME AFTER INFLECTED TRAUMATIC BRAIN INJURY IN SHAKEN BABY SYNDROME: NEUROSURGICAL APPROACH

doi:10.1136/archdischild-2012-302724.1105

F Menegazzo, M Bua, M Rosa Rizzotto, E Sgaravotti, P Facchin, R Faggini. Department of Pediatrics, Child Abuse Unit, University of Padova, Padova, Italy

Background and Aims Shaken Baby Syndrome (SBS) is a severe form of child abuse caused by violent shaking leading to severe head injuries, causing mild-severe long-term disabilities and death. The study aims to explore medium/long-term consequences of SBS comparing children undergoing neurosurgery with hematoma evacuation/cranioplasty with those with hematoma evacuation or no surgery.

Methods A cohort of 21 children with SBS, admitted to Pediatric Department/Padua Hospital (2003–2011), was followed-up. Each clinical record was reviewed collecting information on onset, acute course, ophthalmologic examinations, neuroimaging, treatment and procedures, family history and social background. Cases were followed-up at 3, 6 and 12 months after trauma, every year. The assessment included fundus evaluation and visual function, neuro-radiological exams (MRI).

Results 21 cases were reviewed (M:F=2:1.1), 12 foreigners, 9 italians. Mean age at onset: 5.7 months (range 1.2–18). Mean age at last follow-up evaluation: 30.4 months (range 5–82). Mean follow-up duration: 24.6 months (range 1–73.5). In acute phase 8/19 underwent neurosurgical intervention and 1/21 underwent eye surgery. 20/21 showed retinal hemorrhages, 21/21 cerebral hemorrhages, 11/21 cerebellar hemorrhages, 5/10 spinal subdural hematoma, 4/21 skull fractures, 6/21 other body region fractures. At last follow-up evaluation resulted: 2/21 hemiplegia, 1/21 paraplegia, 1/21 tetraplegia, 2/21 cortical visual impairment, 3/21 visual field deficits, 4/21 strabismus. 10/21 underwent cognitive and behavioural assessment demonstrating in 6 cases global delay and in 4 cases delay in specific functions (locomotor, eye and hand coordination, performance scale). Surgical procedure’s video will be shown.

Conclusions SBS may influence child development and therapeutic surgical approach seems crucial.

1106 IMPACT OF WARMED INHALED GAS FROM THE MECHANICAL VENTILATOR ON ESOPHAGEAL TEMPERATURE DURING WHOLE BODY HYPOTHERMIA FOR HYPOXIC-ISCHEMIC ENCEPHALOPATHY

doi:10.1136/archdischild-2012-302724.1106

During whole body cooling (WBC), the core temperature is monitored with either an esophageal or a rectal probe. Most infants are usually on mechanical ventilation while receiving hypothermia. As the temperature in the esophagus responds rapidly to changes in the ambient temperature, inhalation of warmed gas from ventilator during hypothermia may lead to overestimation of ventilated patients’ actual temperature, causing automated cooling devices to overcool patients well below set temperature targets.

Objective We determined if the esophageal temperature recordings during therapeutic WBC differ between ventilated and non-ventilated infants.

Methods Twenty-two consecutively cooled infants had simultaneous esophageal and rectal temperatures recorded every 4 hours during 72 hours of WBC. The later was deemed to be actual core temperature. Other clinical monitoring and treatment during hypothermia were as per established protocol.

Results Fourteen infants received mechanical ventilation throughout cooling. The remaining 8 infants were on ventilator initially but got extubated and were not on ventilator during 32 to 72 hours section of WBC. Esophageal temperatures were significantly higher than simultaneous rectal temperatures (p<0.01 at each time point) for all 22 infants. However, the esophageal temperatures across every 4 hour time points during 32 to 72 hours section of WBC did not differ between the ventilated (n=14), and non-ventilated (n=8) infants. The magnitude (median, IQR) of the difference between esophageal and rectal temperatures were also similar between the 2 groups.

Abstract 1106 Figure 1 Comparison of E-R (in centigrade) between 2 groups

Conclusions Warmed inhaled gas does not interfere with the esophageal temperature during WBC.

1107 CONTINUOUS CARBON DIOXIDE MONITORING USING FEATURES OF NEONATAL ELECTROENCEPHALOGRAPHY

doi:10.1136/archdischild-2012-302724.1107

Background The continuous monitoring of partial pressure of blood carbon dioxide (pCO₂) in premature babies has proven to be challenging. Spot measurements of pCO₂ can be performed by taking a blood sample. However the frequency of such measurements is limited by their invasiveness.

Aim We aim to develop a continuous non-invasive method of predicting pCO₂ using features of the preterm electroencephalography (EEG) signal.

Methods A regression model was trained on eight 12 hour EEG recordings that contained 22 blood gas measurements in total. All measurements were obtained from babies born before 28 weeks’ gestation and less than 72 hours old. The duration of EEG quiescence

Background There is widespread variation in enteral feeding practices of infants receiving therapeutic hypothermia (cooling) following hypoxic ischemic encephalopathy (HIE). We compared the safety and efficacy of early versus delayed enteral feeding during cooling.

Methods Retrospective case control study (January 2009 – December 2011). Cooled infants at Karolinska Hospital, Stockholm (KH) received early enteral feeding and were compared to similar infants at Princess Anne Hospital (PAH) Southampton, who had delayed feeding (controls). Infants also received early parenteral nutrition in both centres.

Results A complete data set was available for 28/37 infants at PAH compared to 51/51 neonates at KH. Mean baseline parameters at PAH/KH were birth weight (3404.80/3723 g), male/female ratio (50/55 %), umbilical arterial pH (7.1/7.04) and base deficit (–15.65/–12.03).

There were differences in enteral feeding rates at PAH/KH (20.1/91.0%). The mean volume of enteral feeds (mls/kg/day) at PAH/KH on days 1–4 were: 0/2.1, 0.2/6.1, 1.8/10.1, 1.9/17.1.

There were also differences (PAH/KH) in mean time to establish full nasogastric tube feeding (5.9/7.2 days) achieving full oral feeding (controls). Infants also received early parenteral nutrition in both centres.

Conclusions The ability to provide a novel non-invasive continuous monitoring of pCO2 in newborn preterm babies is discussed.

Discussion Clinically graded HIE was associated with markers of liver function. Cooling did not modify these associations. Liver and brain may have different susceptibilities to hypoxic-ischaemia or different responses to cooling.

Conclusion Feeding practices during hypothermia varies between centres. Early enteral feeding during hypothermia is safe and not associated with any additional morbidity. However, delayed introduction of enteral feeds does not delay the time to reach full enteral feeds or prolong the length of stay at hospital.

Results It is shown that by combining the measurements of both a defined period of EEG interburst interval and the relative power of delta EEG frequency band using a multivariate linear regression model, a prediction of pCO2 can be performed. The automatic removal of mechanical artefact and artefact due to other external influences is demonstrated. A regression coefficient (R^2) of 0.64 is obtainable using both the interburst and delta relative power as predictors for pCO2. All variables are significant to within p<0.05. A section of continuous prediction of pCO2 using EEG showing correlation with simultaneous transcutaneous carbon dioxide measurement is demonstrated.

Conclusion The ability to provide a novel non-invasive continuous monitoring of pCO2 in newborn preterm babies is discussed.

Background The safety and efficacy of early versus delayed enteral feeding during hypothermia (cooling) were compared in infants receiving therapeutic hypothermia (cooling) following hypoxic-ischaemic encephalopathy (HIE). We compared the interburst interval and relative power of EEG frequency band using a multivariate linear regression model.
1107 Continuous Carbon Dioxide Monitoring Using Features Of Neonatal Electroencephalography
