The mean pre-ductal saturations were lower than post-ductal saturations in all groups except the group not having a PDA and not on respiratory support (figure 1).

Conclusions The site of measurement can affect the observed oxygen saturation values and hence should be taken in account while bedside monitoring and planning clinical trials.

**Abstract 1795**

**DID VENTILATORY STRATEGY CHANGE DURING THE LAST 5 YEARS IN ITALIAN NEONATAL NETWORK?**

Neonatologia e Terapia Intensiva Neonatale - Fondazione MBBM - Ospedale San Gennaro Monza, Monza; Department of Neonatology, Regional Hospital of Bolzano, Bolzano; AOUM MEYER, Firenze, Italy

**Background** Intubation and mechanical ventilation (MV) are life-saving procedures but are associated with a higher incidence of acute and chronic complications. Thus, non-invasive ventilation (NIV: nasal continuous pulmonary distending pressure, nasal ventilation, or high-flow nasal cannula) is increasingly used.

**Aim** To evaluate changes in ventilatory strategies between 2006 and 2010 in Italian neonatal network (INN).

**Methods** A cohort of neonates <30 weeks gestational age (GA) or <1501 g birth weight (BW), without congenital anomalies, born in 2006 and 2010, assisted in 31 hospitals participating in INN both years, was analysed (N=5459: 1713 in 2006, and 1746 in 2010). Variables were defined according to Vermont-Oxford criteria. Logistic regressions, adjusting for confounders (GA, BW for GA, antenatal steroids, mode of delivery, multiple pregnancy, 1-minute Apgar score, being inborn, sex, intubation in delivery room, RDS, PDA), and clustering for hospitals, were used.

**Results** Between 2006 and 2010 there were no changes in GA or BW (2006: mean GA 29.1 wks; BW 1087 g; 2010: GA 29.2 wks; BW 1083 g), while antenatal steroids increased (from 78.5% to 83.5%). The number of infants receiving any ventilatory support increased from 81.8% to 85.9%. After adjusting for confounders, mortality decreased (Odds ratio=0.75, 95% confidence interval 0.57–0.98) as well as mechanical ventilation (OR=0.72, 95%CI 0.57–0.90) and BPD (OR=0.68, 95%CI 0.54–0.86), while NIV increased (OR= 1.70, 95%CI 1.41–2.04).

**Conclusions** In the last 5 years, we observed a reduction of MV and an increase of NIV use. This was accompanied by a decrease in risk-adjusted mortality and BPD.
The overall mortality rate was 92%, the duration of hospitalization was between one and 137 days.

**Conclusion** In our study, it has been seen that NCPAP may not be an effective ventilation strategy in premature infants who are at the limits of viability. The high proportion of chorioamnionitis in this group may affect the ventilation and the following problems. These babies are needed to be care at very special settings.

**1798** CLINICAL OUTCOMES OF VERY-LOW-BIRTH-WEIGHT INFANTS WHO RECEIVE NON-INVASIVE VENTILATORY SUPPORT

doi:10.1136/archdischild-2012-302724.1798

E Okulu, S Arsan, IM Akin, S Alan, A Kılıç, B Atasay. Department of Pediatrics, Division of Neonatology, Ankara University, Ankara, Turkey

**Aim** To evaluate the clinical outcomes of very-low-birth-weight infants received non-invasive ventilation at delivery room (DR) and NICU.

**Methods** This prospective cohort study included infants born before 29 weeks, and infants born at 29–30 weeks who didn’t receive antenatal steroid (ANS) from January-2009 to December 2011. During resuscitation, stabilization and transport infants were ventilated with a T-piece. All received 100 mg/kg surfactant. If respiratory drive was present, infants were extubated to nasal CPAP(NCPAP). The need for MV within the first 3-days, neonatal morbidities, mortality, and duration of hospitalization were assessed.

**Results** Eighty infants were evaluated. Mean gestational age(GA) and the mean birth weight(BW) of infants were 27.0±2.1 weeks, and 936.5±299.1 g, respectively. ANS was given to 27% of the pregnancies. The presence of PPROM and chorioamnionitis were 57.5% and 34%, respectively. Twenty-three (28.7%) infants could not be extubated at the DR, and mean GA and BW were lower than the infants who could extubate. Ten(17.5%) of 57 infants who were on NCPAP initially needed MV during their first 3-days. There wasn’t any case with air leak. The incidence of pulmonary hemorrhage, FDA, NEC, IVH, BPD, ROF and mortality were 6.2%, 26.2%, 20.1%, 13.8%, 10%, 10% and 38.7%, respectively. The duration of respiratory support was 1–720 hours (median: 29 hours). Mean duration of hospitalization was 34.9±23.4 days.

**Conclusion** Our study demonstrated that NCPAP is an effective non-invasive ventilatory strategy. It didn’t increase the risk of air leak. The incidences of BPD and ROF in our series were lower than reported in ‘NICHD Neonatal Research Network’ data.

**1799** RESPIRATORY SIGNALS FROM THE EXTERNAL BODY SURFACE IN SPONTANEOUSLY BREATHING PRETERM INFANTS

doi:10.1136/archdischild-2012-302724.1799

1^AW Flemmer, ^1^L Owen, ^1^A Schulze, ^1^S Herber-Jonat, ^1^P^G^ Davis. ^1^Div. Neonatology, Prenatal Center, Ludwig-Maximilian-University Munich, Munich, Germany; ^2^Neonatal Research, Royal Women’s Hospital, Melbourne, VIC, Australia

**Background** Synchronized noninvasive ventilation (sNIPPV) might be superior to fixed time-cycled modes. Several body-surface respiratory signals have been suggested for noninvasive synchronization. However, the quality and utility of such signals have not been evaluated comprehensively.

**Methods** Respiratory signals in spontaneously breathing preterm infants (n=9) were recorded simultaneously (i) respiratory impedance plethysmography (RIPabd & RIPchest), (ii) Graseby Capsule (GC), (iii) a strapless piezo sensor (Piezo), and (iv) a fluid-filled esophageal pressure catheter (Pes). A total of 5813 breaths were evaluated. Subsequently, periods of good-quality signals on all recorded channels were analyzed with regard to signal availability, time lag relative to Pes, and variability of signals.

**Results** In all breaths studied 38% of breaths showed valid signals in all channels without movement artefacts. Of all signals, RIPabd indicated the onset of inspiration earliest in time relative to the onset of inspiration detected by Pes (~52±160ms). RIPabd-signal was followed by GC-signal (+10±177ms). Both signals had a reasonable variability. The Piezo-signal was very sensitive and prone to large variations (+70±137ms compared to Pes). RIPchest indicated inspiration later than RIPabd (+104±212ms).

**Conclusion** These data indicate that both RIPabd and Graseby Capsule are suitable surface sensors for non-invasive synchronization of NIPPV whereas a Piezo sensor exhibited large variability. Signals from all studied sensors were only suitable for a limited amount of time.

**1800** SURVEY OF THE CURRENT USE OF N-IPPV IN SPANISH NEONATAL UNITS

doi:10.1136/archdischild-2012-302724.1800

C Carrasco Carrasco, Respiratory Pathology/Surfactant Group of the Spanish Society of Neonatology (Respisur). Neonatology Unit, Sant Joan de Deu Hospital, Esplugues de Llobregat, Spain

**Background** nIPPV is widely spread in Spanish neonatal units. Little evidence about the best mode of delivery or the appropriate ventilatory parameters of nIPPV is available.

**The Aim** of this study was to assess the current use of nIPPV in Spanish neonatal units.

**Methods** A survey was designed and sent by email to neonatal units. The survey collected information about the devices and the ventilatory parameters used to deliver nIPPV over 2010. The use of synchronisation was also interrogated.

**Results** 87 out of 115 questionnaires were answered and returned (75.6%). 71 units used nIPPV (81.6%). Infant Flow® was the most used device (48/71; 67.6%), followed by conventional ventilators (38/71, 53.5%). The initial ventilatory parameters depended on the device that was used. When Infant Flow® was used, PIPs were set between 6 and 10 cmH2O, whereas when a conventional ventilator was used, PIPs varied between 8 and 15 cmH2O. In contrast, PEEP, inflation rate and inflation time were set in a more stable range regardless of which device was used. Regarding synchronisation, only 13/71 units (18.3%) always used synchronisation, whereas 27/71 units (38%) only used it in some cases. The pneumatic capsule was most frequently used when synchronisation was provided with a percentage of 52% (21/40 units).

**Conclusion** The most used device to apply nIPPV in Spanish neonatal units was a variable flow device. Overall, low PIP and low inflation rates were set at the beginning of this therapy. Synchronisation was scarcely used.

**1801** SURVEY OF THE CURRENT USE OF NON INVASIVE VENTILATION IN SPANISH NEONATAL UNITS

doi:10.1136/archdischild-2012-302724.1801

C Carrasco Carrasco, Respiratory Pathology and Surfactant Group of the Spanish Society of Neonatology (Respisur). Neonatology Unit, Sant Joan de Deu Hospital, Esplugues de Llobregat, Spain

**Background** Nasal ways of ventilation are being used to minimize lung damage due to endotracheal ventilation. Both nCPAP and nIPPV are progressively being more used in neonatal units, in spite of the lack of evidence about the best mode of delivery of nasal ventilation or the appropriate ventilatory parameters.

**The Aim** of this study was to assess the current state of the application of nCPAP and nIPPV in Spanish neonatal units.
1797 Do Non-Invasive Ventilatory Strategies Work in Micro-Premature Infants who are at the Limits of Viability?
