British Paediatric Association and British Association of Paediatric Surgeons

Joint Meeting at Aberdeen 9-11 September 1971

The first joint meeting of the two Associations was held in King's College, Aberdeen, on 9 to 11 September 1971. 112 doctors attended, together with many wives and children, the numbers being almost equally divided between surgeons and physicians; a considerable number of overseas BAPS members were present.

The Scientific Meeting was made up of four symposia covering the care of the surgical neonate; accidents in childhood; intravenous feeding; and solid tumours; together with sessions of submitted papers.

Mock Malignancies in the Urinary Tract. D. I. Williams (*London*). The relative success of recently introduced forms of chemotherapy in childhood malignancies has led to their more frequent and earlier use with a considerable risk that they will be used unnecessarily in non-malignant cases and delay correct diagnosis. This is not only unnecessary but can be positively dangerous, particularly in the neonatal cases where the mortality from, for instance, actinomycin D therapy is by no means negligible. The paper is concerned to review the mock malignancies in the urinary tract and to indicate the proper diagnostic approach for suspected cases.

In the kidney any mass can occasionally be suspected of neoplasm, but simple diagnostic tests should sort out the great majority. The misleading ones can be due to vascular anomalies, as in some forms of renal vein thrombosis, to acute infection, as in renal carbuncle, and to hamartoma particularly in the neonate and in later childhood in the multilocular cyst of the kidney. In the retroperitoneal tissues, adrenal haematoma can be misleading, as can lymphangioma and haemangioma on the posterior abdominal wall.

In the bladder there is an important group of cases under the general heading of 'cystitis' (follicular and eosinophilic) which can produce polypoid changes in the bladder mucosa simulating rhabdomyosarcoma. In the posterior urethra a solitary polyp may be large enough to be mistaken for a tumour. Hamartomata in the form

of neurofibromatosis are another pitfall in diagnosis in the lower urinary tract. Inflammatory lesions can also be misleading at this level, such as appendix abscess, pericystitis, and thermometer injury to the rectum simulating tumour in the true pelvis.

Some Problems in Surgical Management of Children with Hiatus Hernia. J. Lari and J. Lister (*Sheffield*). (Page 201 of this issue.)

Choice of Antibiotics in Management of Children with Peritonitis Complicating Acute Appendicitis. H. Steiner (*Newcastle*). There is no general agreement about the type of antibiotics that should be used in the postoperative management of children with peritonitis before information about the sensitivities of the bacteria isolated from the peritoneal cavity is obtained.

This retrospective survey describes the results of treatment with oxytetracycline alone, or in combination with streptomycin in 130 children with peritonitis (among the 372 children with acute appendicitis admitted to the children's wards of the Royal Victoria Infirmary, Newcastle upon Tyne, during January 1963/December 1967). The addition of streptomycin to oxytetracycline increased the percentage of peritoneal bacteria sensitive to at least one of these antibiotics given immediately after operation from 67% to 87%. The incidence of postoperative abdominal sepsis was wound sepsis 26%, pelvic abscess 4%, subphrenic abscess 1%. There was a significant increase in postoperative

abdominal sepsis when inappropriate antibiotics were given immediately after operation, despite appropriate changes in treatment within 48–72 hours of operation based on the sensitivities of the bacteria isolated from the peritoneal cavity. There was no significant difference in postoperative morbidity between children treated initially with oxytetracycline alone and those treated with

this antibiotic in combination with streptomycin.

The potential value of other antibiotics such as ampicillin, chloramphenicol, erythromycin and lincomycin was discussed in relation to the types and the sensitivities of the bacteria isolated from the peritoneal cavity, in particular bacteria of the coliform and bacteroides groups.

Therapeutic Trial on Nephroblastoma

The International Society of Pediatric Oncology (ISPO) is planning a European clinical therapeutic trial on nephroblastoma. These tumours may be treated by surgery, radiotherapy, and chemotherapy. However, there are some unanswered questions as to the value of different forms of administration of radiotherapy and chemotherapy, which the ISPO believe could best be elucidated by a prospective clinical trial.

At the ISPO meetings in Madrid in 1969, Lyon in 1970, and Mainz in 1971, the purpose, scope, and outlines of the trial were discussed and agreed upon. The main purpose is to decide whether (a) preoperative and postoperative radiation therapy yields better results than postoperative irradiation alone, and (b) multiple courses of actinomycin D therapy are more successful in preventing metastases and recurrences than one single course after surgery.

The reliability of such a trial depends obviously on the

amount of material available for analysis. The ISPO invites anyone who wishes to participate in the trial to write for further information to: Dr. P. A. Voûte, Emmakinderziekenhuis Spinozastraat 51, Amsterdam, Holland, or to Dr. J. Lemerle, Institut Gustave Roussy, 94-Villejuif, France.

For reference see J. Lemerle (1971). Therapeutic trial and prospective study on nephroblastoma: a scheme of the International Society of Pediatric Oncology. (S.I.O.P.). *U.I.C.C. Bulletin Cancer*, 9, No. 3, October.

Editorial Note: United Kingdom readers may also like to be reminded of the therapeutic trials already in progress on nephroblastoma (Wilm's tumour) and neuroblastoma, organized by the Medical Research Council Working Party on Embryonal Tumours in Childhood. For details, see *Archives of Disease in Childhood* (1970), 45, 821.
