G376 ABSTRACT WITHDRAWN

G377 THE ROLE OF CARDIOPULMONARY EXERCISE TESTING IN CHILDREN WITH CYSTIC FIBROSIS

1 E Weir, 1 P Burns, 1 D Young, 1 JY Paton, 1 A Devenny, 1 Respiratory Paediatrics, Royal Hospital for Sick Children, Glasgow, UK; 2 Department of Mathematics and Statistics, University of Strathclyde, Glasgow, UK

10.1136/archdischild-2015-308599.332

Introduction Cardiopulmonary exercise testing (CPET) is the gold standard test of aerobic fitness in Cystic Fibrosis (CF). CPET is measured by peak oxygen uptake (VO2 peak) during maximal exercise. It can be used to identify the cause of exercise intolerance, prescribe exercise programmes, evaluate therapeutic interventions1 and predict prognosis.2 The American Thoracic Society defines a normal VO2 peak as >84% predicted.3 In our centre, CPET was included in the CF annual reviews from 2013. Currently no guidelines exist as to the frequency of CPET in CF patients.

Aims To determine whether CPET was a useful and feasible routine test in children with CF and to assess whether VO2 peak correlated with Forced Expiratory Volume in 1 s (FEV1), disease severity, gender, genotype or previous intravenous antibiotics.

Method A pilot observational study was performed. Body mass index (BMI) was used as a marker of disease severity. Genotype was divided into 3 groups; DF508 homozygous, heterozygous and all other genotypes. Data was retrieved from case notes and our CF database.

Results 38 patients (17 male, 21 female) underwent CPET. Age range 7–14 (mean 9.9) years. 36/38 had technically satisfactory CPET. Mean VO2 peak was 107% predicted, standard deviation 18%. Only 8% had an abnormal VO2 peak. Mean FEV1 was 91% predicted, standard deviation 15%. There was no relationship between VO2 peak and FEV1 [p = 0.297] or BMI [p = 0.382] (Pearson correlation). Additionally, no correlation was demonstrated between VO2 peak and genotype [p = 0.236] (one-way ANOVA), gender [p = 0.902] or patients who had received at least one course of intravenous antibiotics in the past year [p = 0.253] (two-sample T test).

Conclusions CPET is a feasible test with 95% of our patients achieving technically satisfactory assessments and reassuringly, VO2 peak was largely normal. We could not demonstrate a relationship with FEV1 or disease severity although our study is limited by the small sample size. It is recognised that the CF annual review is already a long day for patients and we plan to reserve CPET for those showing exercise intolerance rather than performing it annually.

Aims This study aimed to characterise seasonal variation, co-infection rates, susceptible groups (by gender, age and co-morbidities) and selected clinical features of childhood human metapneumovirus (HMPV) infection.

Methods The study was a retrospective analysis of 656 HMPV-positive respiratory samples collected from paediatric patients aged 0–15 years processed from January 2010 to December 2013 using real time PCR assays. In addition, 200 HMPV-positive samples from January 2012 to January 2013 were cross-referenced with electronic discharge summaries and descriptive statistical analyses of selected clinical features were performed.

Results 377 of 656 (57%) HMPV-positive samples were from male patients. HMPV was most frequently detected in children aged 6–9 months and the median age of patients studied was 15 months. Seasonal patterns of HMPV infection varied from year to year. The peak in HMPV-positive isolates occurred between February and May. 117 of 656 (17.5%) samples were positive for other respiratory viruses in addition to HMPV. The most common co-infections were due to rhinovirus (58/656, 8.84%) and adenovirus (36/656, 5.49%).

81 (40%) of the 200 fully-characterised patients were hospitalised, 7 (3.5%) of whom required intensive care (ICU) or high dependency (HDU) admission. Rashes were reported in 14 (7%) and febrile seizures in 9 (4.5%) of 200 patients. These clinical features were more common in children with co-infections [6/40 (15%) and 4/40 (10%) respectively].

Conclusions Male gender is suggested as a predisposing factor for HMPV infection, along with younger age. Seasonal variation of HMPV infection in Scottish children appears different to the reported winter peaks of other studies, with peak incidence occurring between February and May in our dataset. Co-infection is common, and most frequently associated with rhinovirus or adenovirus. Rashes and febrile seizures are relatively common in HMPV-positive patients, especially those co-infected with other respiratory pathogens. Human metapneumovirus is a significant cause of morbidity in children. Further, larger-scale epidemiological research appears warranted, along with work to develop new therapies aimed at targeting HMPV.

G379 DESCRIPTIVE ANALYSIS OF ADHERENCE WITH NON-INVASIVE VENTILATION IN CHILDREN

MJ Vincent, PD Davies, NG Gibson, A Morley. Paediatric Respiratory Medicine, Royal Hospital for Sick Children, Glasgow, UK

Aims Home non-invasive ventilation (NIV) is an established treatment for children with sleep-disordered breathing. There is...
HYPONATREMIA

Problem

4 year old child transferred to PICU after space occupancy cranial surgery. On day 2 post operatively was noted to have very high urine output with falling serum sodium. His urine output was very variable and ranged from 3 ml/kg/hour to 17 ml/kg/hour. He had very high urinary sodium content.

Clinical context

- Falling sodium
- High urine output
- Low plasma osmolality

Assessment of problem and analysis of its causes

- Hyponatremia in Patients with Neurologic Disorders
- Inappropriate secretion of antidiuretic hormone (SIADH)
- Cerebral salt wasting (CSW) syndrome

The distinction between these two conditions is important because their treatments are different. It is not possible to distinguish CSW from SIADH based on serum and urine laboratory findings alone, because their associated abnormalities are identical. For this reason, accurate determination of the patient’s volume status is the key to differentiating these syndromes.

Fundamental difference between the two processes is extracellular fluid volume status. Patients with CSW have hypovolemia compared with patients with SIADH, who have euvolemic or mild extra cellular fluid expansion.

The mainstay of therapy for CSW is replacement of the sodium and water that is lost as a result of pathologic natriuresis and diuresis. This is in direct contrast to the treatment of SIADH, the crux of which is free water restriction.

CVP-directed treatment of hyponatremia and volume status in such patients is effective.

Intervention New guidelines for cerebral salt wasting introduced in PICU guidelines.

Lessons learnt Consider CSW in children with low sodium and high urine output, measure volume status, in PICU setting with CVP measurement.

G380(P) HYPONATREMIA – CEREBRAL SALTS WASTING

G381(P) IMMUNOPROTECTIVE EFFECTS OF INHALED NITRIC OXIDE IN NEWBORNS WITH RESPIRATORY DISEASES ON MECHANICALLY VENTILATION

M Puhtinskaya, V Estrin, Department of Anesthesiology and Intensive Care, Research Institute of Obstetrics and Pediatrics, Rostov-on-Don, Russia

10.1136/archdischild-2015-308599.336

Introduction

This study presents the results of the influence of inhaled nitric oxide (iNO) on the immune system of infants with respiratory diseases on mechanically ventilation (MV).

Purpose

Decrease neonatal mortality.

Materials and methods

In a controlled, randomised, blinded clinical trial 37 newborns with respiratory diseases on MV were included. In group I 20 patients received iNO (10 ppm, 24 h; “Pulmonox mini”, “Meser II NO Therapeutics”, Austria). Newborns in group II (n = 17) did not receive iNO. On admission and at 3–5 days, subpopulations of lymphocytes were studied by one-parameter immunophenotyping using reagents company Immunotech Beckman Coulter (USA): CD3, CD4, CD8, CD14, CD19, CD34, CD56, CD69, CD71, CD95 monoclonal antibody, the relative content of lymphocytes in apoptosis using AnnexinV + labelled FITK and propidium iodide (PL+), labelled with PE (Saltag, USA). The statistical power of the study was 80% (α ≤ 0.05).

Results

In group I an increase of mature monocytes (CD14+, q = 0.05) was demonstrated.

Duration of MV was 4.1 ± 1.4 days in group I and 18 ± 5.4 in group II. All newborns in group I survived and had no septic complications. None of the patients showed clinical or laboratory evidence of adverse effects of iNO. In group II 7 newborns died, 5 developed neonatal sepsis.

Conclusion

Inhaled NO in mechanically ventilated newborns increased the relative content of mature macrophages and decreased the number of lymphocytes in apoptosis. Most importantly, the incidence of sepsis and fatal outcome was reduced in iNO-treated newborns.
