Patients and methods Have a 94 girls 3–6 years with VV, of which 1 group (n=52) – VV on the background of the UTI, group 2 (n=42) - isolated VV the assessment of biocenosis of the vagina by microscopy and PCR. Local antibiotic therapy was combined with the use of interferon alpha 2b 500 000 ME 2 times a day for 5 days, then 1 time a day – 5 days. Prevention of exacerbation of UTI was carried out by phytopreparation CAN-UTI-7 15 drops 3 times a day for 4–6 weeks.

Results In girls with VV and UTI, compared with group 2, the frequency of chronic VV was high (57.7% and 29.6%, p<0.05), the frequency of relapses (46% and 14.8%, p<0.05). In both groups, growth of opportunistic microflora and facultative aerobes >10^5 CFU/ml was revealed. St. epidermidis, E. faecalis were sown more often in isolated VV. The detection rate of E. coli, Candida alb. in group 1 was higher than in group 2. After treatment in group 1, E. coli decreased from 6.8±0.05*10^6 to 1.7±0.03*10^5 CFU/ml (p<0.05), microbial contamination - from lg 5.6±0.07 to lg 2.4±0.01 CFU/ml (after 1 month), lg 2.1±0.1 CFU/ml (after 12 months) (p<0.05).

Conclusion Complex therapy of girls with UTI improves the condition of the vaginal biotope, reduces the rates of microbial colonization and the number of relapses of VV.

P588 HERPES ZOSTER IN A 2-MONTH-OLD INFANT: A CASE REPORT

1Alef Ben Thabet, 1Chiraz Regaieg*, 1Amel Ben Hamed, 1Menel Charfi, 1Nedia Himida, 1Hamida Turk, 1Amira Bouraoui, 2Abdelatif Gargouri, 1Department of Neonatology, Hedi Chaker Hospital, Sfax, Tunisia; 2Department of Dermatology, Hedi Chaker hospital, Sfax, Tunisia

Background Herpes zoster (HZ) is a cutaneous viral infection of the skin that presents in a dermatomal distribution. It represents reactivation of herpes varicella zoster virus that has continued to exist in a latent form in the neurons of the posterior root ganglia. Although it is rare to see HZ in children, cases have been reported after exposure to varicella zoster in utero or during the first months of life.

Objective The purpose of this report is to present a case of herpes zoster in a 2-month-old infant, conservatively managed without oral antivirals, and its 5 years follow-up, demonstrating no sequelae or recurrences.

Case report A 2-month-old female infant presented with skin lesions in the chest. His mother developed a varicella infection 20 days before delivery. The child was asymptomatic at birth. Physical exam noted a fever and skin lesions made of grouped vesicles on erythematous plaques. The characteristic herpetiform lesions distributed in the dermatome of the left hemi-chest. The infant was treated by only local antiseptic treatment. The lesions were completely resolved in 2 weeks. After 5 years of follow-up the child has no sequelae, such as postherpetic neuralgia, or recurrence.

Conclusion After maternal varicella during pregnancy, herpes zoster may occur in the first year of life in a completely asymptomatic child at birth proving in utero infection. The presentation of the rash is characteristic; but otherwise, the condition differs from that in adults in that it is mild and not associated with postherpetic neuralgia. In uncomplicated cases, conservative treatment measures support the quick resolution with no sequelae.

P589 CUTOIS MARMORATA TELANGIECTATICA CONGENITA

1Amel Ben Hamed, 1Alef Ben Thabet, 1Chiraz Regaieg*, 1Menel Charfi, 1Nedia Himida, 2Abderahmen Masmoudi, 1Hamida Turk, 1Amira Bouraoui, 2Abdelatif Gargouri, 1Department of Neonatology, Hedi Chaker Hospital, Sfax, Tunisia; 2Department of Dermatology, Hedi Chaker hospital, Sfax, Tunisia

Background Cutis marmorata telangiectatica congenita (CMTC) is a rare congenital cutaneous vascular anomaly. About 300 cases were reported in the literature. It is associated persistent cutis marmorata, telangiectasia, and phlebectasia.

Case report We report a case of male neonate who has multiple bruises and purple macules on the skin anastomosed making a reticulated appearance as a spider's web, those skin lesions cover the trunk and legs but did not affect the face and did not disappear during the warming of the baby. Limits between normal and involved skin were atrophic. Given the constellation of clinical finding, Cutis Marmorata Telangiectatica Congenita (CMTC) was diagnosed.
