4. To provide educational information on healthy eating/further weight management options.

**Methods** Children aged two years or older attending the Emergency Department were identified. Parents completed a survey indicating the perceived weight status of their child. The height and weight of the child were recorded, and the BMI and standardized body mass index (BMI SDS) were calculated using the 'Measure Me' phone application and communicated to the parents. Children were offered a ‘Healthy Ireland’ food pyramid sticker. Parents of those overweight/obese children identified were provided with details to be referred onto Temple Street Hospital Outpatient Services for further weight management.

**Results** 101 children in total participated. 17.8% (18/101) were classified as overweight/obese, with a standardized BMI above the 91st centile. Of those overweight/obese; 50% (9/18) of parents incorrectly identified their child to be of normal weight status. Of the parents who accurately identified their child as overweight (9/18), 77.8% (7/9) indicated they perceived their child to be 'mildly' overweight. Objectively 85.7% (6/7) of these were obese with a BMI SDS above the 95th centile. In total 83.3% (15/18) of the overweight children had a standardized BMI above the 95th centile. 83.3% (15/18) of overweight/obese children accepted educational information.

**Conclusion** In keeping with Questly M. et al.’s study a large proportion of children were objectively overweight/obese with a BMI SDS above the 91st centile. However half of the parents failed to accurately identified their child’s overweight/obese status. Although the remainder of parents accurately identified their child as overweight, a large proportion indicated that they perceived their child to be ‘mildly overweight’. The vast majority of these children were obese with a BMI SDS above the 95th centile. The high rates of parental acceptance of educational information would suggest a willingness to be further educated on weight optimization in children.

**P659** CORNELIA DE LANGE SYNDROME AND SPONTANEOUSLY REGRESSIVE BRONCHOGENIC CYST ABOUT A UNUSUAL CASE

1Faiza Safi, 1Sahar Trichilli, 1Manel Hsairi, 2Lamia Gargouri, 2Chiraz Regaieg*, 1Mahdi Ben Dhaou, 2Abdelatif Gargouri, 3Riadh Mahiri, 1Abdelmajid Mahfouf. 1Pediatric Emergency and Resuscitation Pediatric Service, Hedi Chaker Hospital, Sfax, Tunisia; 2Neonates Intensive Unit Care, Hedi Chaker Hospital, Sfax, Tunisia; 3Pediatric Surgery Department, Hedi Chaker Hospital, Sfax, Tunisia

**Introduction** Cornelia de Lange syndrome is characterized by intra uterine and postnatal growth retardation, developmental disorder, facial dysmorphism, hypertichrosis, and organ malformations. The association with a bronchogenic cyst is unusual.

**Case report** This is an 8-month-old male, born at term from a non-consanguineous marriage. He was hospitalized twice for recurrent pneumonitis. It was addressed for further exploration. On clinical examination, he had microcephaly, a low set of hair on the forehead, arched and confluent eyebrows, long eyelashes, a wide nose root, antverted nostrils, a long and bulging philtrum, a mouth falling at the corners and a very thin upper lip, a low implantation of the ears and a microretrogatism. He was puny with a weight loss of -4 DS. Biologically, the infectious balance was negative. An abdominal ultrasound performed was without abnormalities as well as the transfontanellar ultrasound. A thoracic CT showed a large right mediastinal hilar cystic mass measuring 69x68x44 mm with fluid density and regular clean wall enhanced after injection of contrast agent dealing with a bronchogenic cyst. The therapeutic abstention was opted. The evolution was marked by the spontaneous regression of the cyst.

**Conclusion** Cornelia De Lange syndrome is rare with variable severity. The association with bronchogenic cyst which had spontaneously regressive evolution is a rare entity.

**P660** ABCESS OF THE KIDNEY, A DIAGNOSIS NOT ALWAYS EVIDENT!

1Faiza Safi, Lamia Gargouri, Manel Hsairi, Chiraz Regaieg*, Bayen Maalej, Abdelmajid Mahfouch. Hedi Chaker Hospital, Sfax, Tunisia

**Introduction** Kidney abscess is defined as a suppurate lesion collected in the renal parenchyma. It is a rare pathology in pediatrics. We report four cases of renal suppuration.

**Material and method** This is a retrospective study over a period of 9 years (2010-2018) collaging all cases of renal abscess having been hospitalized in the pediatric ward, emergency and pediatric resuscitation of Sfax.

**Results** We collected 4 cases of renal abscess. These were two boys and two girls. The average age was 5 ½ years with extremes ranging from 3 ½ years to 10 years. The delay of diagnosis was estimated at an average of 19 days. Fever and
