1042 DOES THE USE OF TECHNOLOGY IMPROVE GLYCOXYLATED HAEMOGLOBIN LEVELS IN CHILDREN WITH TYPE 1 DIABETES MELLITUS (T1DM)?

Khalida Yasso1, Florence Scott2, Mark Deakin3, Fulya Mehta4, Atrayee Ghatak4, Princy Paul1. 1St Helens and Knowsley Lead Employer; 2St. Helens and Knowsley Lead Employer; 3Alder Hey Children’s Hospital; 4Alder Hey children’s hospital

Background The 2017/18 National Paediatric Diabetes Audit (NPDA) in the U.K. reported that on average, insulin pump users with continuous glucose monitors achieved lower HbA1c levels compared to manual glucose checks.

Objectives This study involves children and young people (CYP) aged below 19 years with Type 1 Diabetes Mellitus (T1DM) attending a tertiary UK hospital. The aim was to compare median HbA1c levels of glucagon monitoring device in use, which included: manual checks, Dexcom G6, Libre Flash, insulin pumps with Low Glucose Suspend (LGS) and Closed Loop Systems (CLS). The median HbA1c was calculated for each group and analysed.

Methods This was a retrospective observational study using our hospital diabetes database to identify patients. Inclusion criteria were T1DM patients on multiple dose insulin (MDI) or insulin pump regimens. 405 patients were categorised by their insulin regimen and type of glucose monitoring devices.

Results Of the 405 patients included, 187 (46%) used continuous subcutaneous insulin infusions (CSII) and 218 (54%) used multiple daily injections (MDI) regimens. Table 1 demonstrates the median HbA1c for each group of patients. The lowest median HbA1c was in the pump group using a closed loop system, while those on MDI, even with Libre Flash, struggled with higher HbA1c levels.

Conclusions As per the published studies, this work supports the use of advanced technology in diabetes care and of closed loop systems to provide the best possible glycaemic control. Interestingly, despite Dexcom G6 being more expensive than Libre Flash, this small study has not shown any advantage for the use of Dexcom G6 in terms of diabetes control for CYP on insulin pumps.

1043 SUBOPTIMAL ALLERGY KNOWLEDGE REINFORCES PENICILLIN ALLERGY LABELS IN CHILDREN

Kene Maduemem1, Eliza Magnusen2, Umar Khan3, Tom Beatie4. 1Birmingham Children’s Hospital; 2Leicester Royal Infirmary; 3University of Edinburgh

Background Penicillin allergy (PenA) is the most common reported drug allergy in acute settings.1 Delayed non-severe maculopapular rash is the most reported symptom. However, this is also a common feature of viral illness. The problem faced by clinicians is to determine whether the rash is allergic in nature, thereby affecting therapeutic decisions.

Objectives This study investigates how this conundrum is approached by front-line clinicians.

Methods A cross-sectional anonymised survey of prescribers working in a tertiary paediatric emergency department was performed. A clinical vignette described the choice of antibiotic for a child who previously developed a delayed non-severe maculopapular rash after administration of penicillin. Likert scale of agreement was used to evaluate the use of allergy pertinent questions.

Results Sixty-two prescribers with varied clinical grades responded. All respondents have encountered children with reported PenA in clinical practice. Twenty-six (42%) respondents would prescribe a penicillin-based antibiotic in the clinical vignette. The most sought allergy information was related to symptom(s) of the reaction (55/62; 89%). Thirty-eight (61%) respondents would inquire regarding when the reported reaction occurred. Whilst 38 (61%) prescribers would clarify the time interval between ingestion and symptoms, a lower proportion (24/62; 39%) would verify if allergy referral or testing had been done.

Conclusions This single centred survey confirmed regularity of contact with reported PenA in acute settings. A suboptimal rate of allergy focused history was highlighted. Allergy education will be an invaluable first step in safe antibiotic allergy de-labelling and antimicrobial stewardship promotion.
