

Appendix 1

Comparison of non-AKI and AKI groups

Median urine ACR was higher in those with AKI ($p=0.04$) although there was no difference in the presence of dipstick proteinuria or haematuria between groups. Median urine RBP/creatinine and NAG/creatinine ratios were higher in the AKI group although the difference between groups did not reach statistical significance. There was no difference in those with abnormal ultrasound findings, or the number of nephrotoxic medications received, between groups. None of the AKI group had sustained hypertension during admission.
