Sources of error in estimation of glomerular filtration rate from plasma creatinine concentration in children

Sir,

Counahan et al. (1976) introduced a new simple method of estimating glomerular filtration rate (GFR) by means of plasma creatinine concentration (Pc) and body height (Ht) using formula GFR (ml/min per 1.73 m²) = 0.43 Ht (cm)/Pc (mg/100 ml). Recently Széld and Méhes (1977) showed in a large group of children without renal disease that the conventional 24-hour creatinine clearance correlates well with the GFR estimated by the Ht/Pc method. However, the usefulness of the latter method demands that Pc be stable and that creatinine production be within normal limits, so that Pc reflects only the excretory function of the kidneys.

Congenital nephrotic syndrome of Finnish type (CNF) is characterised by massive proteinuria, poor somatic growth, and slow deterioration of renal function (Hallman et al., 1973; Huttunen, 1977). On account of the decreased muscular mass in proportion to body weight, creatinine production and consequently Pc of patients with CNF is low.

We have compared the GFR estimated by the Ht/Pc method with the 24-hour endogenous creatinine clearance (24-hour Ccr) in 61 measurements of 15 CNF children under the age of 2 years, and in 67 children and young adults with acquired renal disease aged from 9 months to 20 years. Plasma and urinary creatinine were determined as true creatinine after absorption of noncreatinine chromogens by Lloyd’s reagent (Henry et al., 1974). The results are shown in the Fig. The correlation between the two methods is satisfactory in both groups, but in CNF children the mean of the 24-hour Ccr is 17.3 ml/min per 1.73 m² lower than that of the GFR estimated by the Ht/Pc method; while in the children with acquired renal disease the 24-hour Ccr is 8.2 ml/min per 1.73 m² higher than the result from the Ht/Pc method on average. The mean of Pc in CNF children was 0.41 mg/100 ml (36.2 μmol/l) with a range of 0.16–1.84 mg/100 ml (14.1–162.7 μmol/l), and that of the children with acquired renal disease 0.69 mg/100 ml (61 μmol/l) with a range of 0.26–7.40 mg/100 ml (23–654 μmol/l). The 24-hour urinary excretion of creatinine per kg body weight of CNF children was 8.6±2.5 mg and that of the children with acquired renal disease 16.5±4.1 mg; the difference between the two groups is significant at the level of P<0.001.

Creatinine is to some extent excreted by the renal tubular cells (Arant et al., 1972). Thus somewhat higher values are expected from the conventional 24-hour Ccr than from the Ht/Pc method in children with normal creatinine production. On the other hand, in CNF children with low creatinine production the Ht/Pc method obviously overestimates the true GFR, and in this peculiar situation the conventional creatinine clearance is more accurate than the Ht/Pc method in the estimation of GFR. No doubt the Ht/Pc method is reliable and generally suitable to clinical work, but it must be remembered that it gives false results when Pc is not in equilibrium or when the endogenous creatinine production is low.

Nystatin resistance in thrush

Syr,

Dr R. F. Jennison, in his useful review of thrush in infancy (Archives, 1977, 52, 747), did not mention the occurrence of nystatin resistance. In a recent case I was so impressed by the failure of nystatin, applied by an intelligent mother, to clear the perineal and oral thrush that I sent the baby with his thrush to the laboratory at the Sheffield Children's Hospital to have a culture made. There was a growth of *Candida albicans* resistant to nystatin (MIC 100 U/ml), but sensitive to amphotericin B (MIC < 0.2 μg/ml). The thrush cleared promptly with amphotericin.

European Congress of Obstetric Anaesthesia and Analgesia

Sir,

It is intended to hold the first of what is hoped will become a sequence of congresses of this type at the National Exhibition Centre, Birmingham, England, in September 1979. The programme of the congress is designed to be of interest to anaesthetists, midwives, obstetricians, and paediatricians. Its major objective is to provide a forum whereby representatives of these specialties can discuss problems of mutual interest in respect to standards of safety and effectiveness of clinical practice, training, and staffing.

The congress will last for 4 days, and the general titles of the topics to be discussed are: (i) pain relief during labour; (ii) identification of, and supportive therapy for, the fetus at risk; (iii) anaesthesia for operative delivery; (iv) neonatal resuscitation; (v) intensive care of the seriously ill neonate; (vi) intensive care of the seriously ill parturient.

The meetings are being devised in such a way as to encourage the active participation of all delegates in discussions which will follow each formal presentation. The prepared papers will be presented by anaesthetists, midwives, obstetricians, and paediatricians who are currently in practice in Europe. Simultaneous translation into English, French, and German will be available. A large exhibition will be sited within the congress hall, which will be of interest to all delegates. There will also be a full calendar of social events each day for delegates' nonparticipating companions and each evening for the entire company.

More detailed announcements will be forthcoming during the next few months. This preliminary notification is to enable interested readers to make a note of the dates (probably 18–21 September 1979) and, if they so wish, to write to me personally to request advance notice of the details of registration.
