Correspondence

birthweight; in 3 out of 4 babies in whom I attempted to pass the tube the tip lodged in the first part of the duodenum and would not negotiate the duodenal loop. It is possible that this difficulty could be overcome by using a tube with a shorter weight at the tip.

I have had no experience with NJ tube feeding in babies being mask ventilated, but Wells and Zachman1 and Beddis and McKenzie2 reported considerable difficulties and a high complication rate; this would seem to be a contraindication for transpyloric feeding.

Intractable diarrhoea of infancy and latent otomastoiditis

Sir,

Dr Dodge's commentary has encouraged me to report my own experience in the same field as Salazar de Sousa et al.1 The connection between intractable diarrhoea and latent otitis media is well known here also. In the 1930s several articles were published about it in Hungary.

After treatment using fluid and electrolytes had been introduced, we found3 that if an infant failed to recover after rehydration therapy latent otitis media should be considered. However, an immediate operation resulted in rapid improvement in the patients.

After the second world war latent otomastoiditis with diarrhoea was common. At that time our patients were dystrophic and their general condition was poor as a result of lack of appropriate infant food, unsatisfactory factory hygiene, and the inequality of parents. This also accounted for the fact that the late mortality rate in infants was 10 times higher than it is now. Salazar de Sousa et al.1 mentioned that their patients also suffered from malnutrition. For 15–20 years, no such patient has presented and thus latent otomastoiditis has almost disappeared. However, it should not be forgotten, and we are grateful that our attention has been drawn to this problem.

Sir,

It is well known that latent otomastoiditis is one cause of failure to thrive, and so too, although less often, is it a cause of diarrhoea. Its disappearance from paediatric literature was only temporary. Referring to the paper by Salazar de Sousa et al.1 we wish to draw attention to the following aspect of otitis and diarrhoea.

In Peru malnutrition is common in infants and children and all necropsies on children who had suffered from severe malnutrition showed latent otomastoiditis. A number of infants in hospital with severe malnutrition was carefully examined; about two-thirds also had diarrhoea, partly meeting the criteria of intractable diarrhoea. No normal antomastoid X-ray film was found in the entire group, and all leucocyte counts were normal. Antotomy was performed on a few patients and the remainder were treated for malnutrition only, firstly by parenteral and, later, by oral refeeding. This resulted in recovery from both otitis and diarrhoea, and consequently we feel that diarrhoea and otomastoiditis can be two unrelated sequelae of a single cause—malnutrition. As Salazar de Sousa et al. gave no precise details of the nutritional status in his patients, malnutrition before the onset of severe diarrhoea seems possible. However, leucocytosis in these cases could suggest a different pathogenesis.

Professor Salazar de Sousa comments:

I agree that failure to thrive (without diarrhoea) may be associated with latent otomastoiditis. Recently we had a patient in whom antotomy showed an ear infection and was followed by rapid weight gain.

The necropsy findings in severely malnourished Peruvian infants are not surprising, since they are similar to the findings of Parrot.3 The possibility of spontaneous healing of latent otomastoiditis was shown by Lévesque et al.2 by means of diagnostic and sequential needle aspirations of the antrum in infants who recovered without need of antotomy. It must be admitted that an unknown, but high proportion of infants suffering from malnutrition, diarrhoea, and latent otomastoiditis may recover only with medical treatment. However, other patients did not tolerate ear infection so well and they present a remarkable resistance to treatment; their recovery is dependent on antrum surgery.3 Our present experience with such infants is confined to 16 cases, 13 of whom were submitted to antotomy. In each of the 11 survivors the response to surgery was the same: clearing of diarrhoea within 4 days, disappearance of fever (when present) the following day, and rapid weight gain. In these cases clinical improvement is unlikely to have been

due to any factor other than antrotomy. In summary, we may have to deal with two sorts of infants: in the first, diarrhoea and latent otomastoiditis can be the unrelated sequelae of malnutrition and recovery from both can be achieved by nutritional improvement; in the second, latent otomastoiditis may perpetuate both the diarrhoea and the malnutrition and recovery be dependent on antrotomy.

I do not know why leucocyte counts were normal in the patients seen by Dr Alarcón but were consistently increased in ours. However, the relationship between leucocytosis and latent otomastoiditis was in no doubt, as shown by the rapid fall in leucocyte counts after antrotomy.
