Book reviews

Pressures are being put on maternity hospitals to provide high standards of care for very ill and often very preterm babies. These pressures will not go away; in fact efforts to centralise neonatal intensive care have the paradoxical effect of making greater demands on paediatric and nursing staff at district maternity hospitals who feel duty bound to give babies a chance and to provide at least short-term intensive care until help is forthcoming from the regional centre.

This manual of neonatal intensive care will enable the resident paediatrician to endure his punishment on the neonatal unit with much greater confidence. Neonatal medicine, far from being highly specialised, is the last bastion of the general physician. A knowledge of physiology of the different organ systems during adaptation to extrauterine life is very necessary and enough is included in this book to help the resident understand the common neonatal disorders. The author has managed to cram virtually all the topics relevant to neonatal intensive care into 250 small pages and keep the text readable.

The chapters on resuscitation and respiratory disorders are particularly helpful, with a lucid account of the use of assisted ventilation. One of my obsession-compulsive behaviour traits is that I cannot pass flow diagrams without tracing every stream of arrows from their source to destination; some of the author's compositions were a problem. I narrowly escaped becoming trapped in the 2-page spread of guided missiles which showed what to do when an infant deteriorates on a ventilator. Dr Pickering's chapter on congenital heart disease is instructive; did you know that each of the major types of cyanotic congenital heart disease begins with the letter 'T'?

It is clear that the author has spent much time by the incubator resolving clinical problems, and this excellent book contains the nuances of neonatal care that are rarely found elsewhere; for me that is one of its greatest strengths. It will strongly appeal to resident paediatricians.

My only complaint is that the cover of the book is pink! I suppose this was necessary for balance because throughout the text babies are referred to as 'he'. May I urge the publishers to go the whole hog and produce the next edition in an appropriate shade of blue?

MALCOM CHISWICK

This book is intended primarily for district medical officers in developing countries responsible for organising and administering district mother and child health services. It provides accounts of the background to paediatric disease in developing countries followed by sections on specific infections and diseases of systems. These last chapters contain accounts of the epidemiology and the pathogenesis of disease, and variable amounts of instruction on the diagnosis and treatment of individual conditions.

The doctor in a developing country is confronted by the dilemma of how to divide time between the organisation of preventive medical services and the treatment of sick patients. There is a similar dilemma here in that the author seems undecided whether to write on the management of acute paediatric disease or on the organisation of paediatric health care. The management of specific conditions is dealt with somewhat patchily. There is no account of tetanus; bronchiolitis gets all-embracing treatment; tuberculous meningitis is dealt with in two brief paragraphs. Some treatment regimens are unusual and confusing (especially for digoxin on pages 236 and 238). The parts relative to paediatric services seem to lack practical detail. Nutritional rehabilitation services and under fives clinics occupy only half a page each although we are told that 'the importance of the under fives clinic . . . has not been sufficiently appreciated'. The final section which covers 'Provision of care' is so crucial that it demands more than the final 7 pages.

This book is one of a series of manuals available at a reduced price in developing countries; this is good. Nevertheless, despite the price and clear, attractive layout, those wondering whether to buy it would be wise to see it first so as to decide whether it really would be of value in their paediatric practice.

ELIZABETH POSKITT

The difficulties encountered in reviewing this book in no way reflect on its qualities. Since paediatrics is an age-related rather than a system-related specialty the reader will most appreciate those chapters which deal with his own particular interests within the specialty. However, the appearance of a new number of Recent advances in paediatrics is an event for all paediatricians in the UK and for many abroad. This maintains and, in many ways, improves on the standards of earlier numbers in scope and in the quality of the contributions.

In twelve chapters the volume contains authoritative reviews of aspects of paediatrics as diverse as interpretation of perinatal mortality statistics, reviews of clinical practice in its scientific basis in neonatal paediatrics, paediatric cardiology, chronic diarrhoeal disease, liver disease, and malignant diseases in childhood. Other contributions include thoughtful reviews of diabetes of childhood, the role of immunology in paediatrics, and chronic central nervous system disease in childhood. It is also valuable to the paediatrician of the 1980s to have a discursive chapter on the place of health education. It is perhaps one of the outstanding features of this volume that it provides such a critical review of many of the most controversial aspects currently in paediatric practice. The first chapter on problems and interpretation of perinatal mortality statistics treats the subject with a delicate and informed scepticism and should be required reading for individuals or groups discussing priorities for health care and who draw facile conclusions on

At an absolute minimum 3 per thousand children in the UK have been sexually abused at some time in their childhood; this was the conclusion drawn by Mrazek, Lynch, and Bentovim from a survey they conducted by questionnaire and which they report in chapter 4 of this book. Despite this, well over two-thirds of the 143 British paediatricians replying to the questionnaire had never seen a case; the authors suggest that there is a denial and avoidance of child sexual abuse similar to the attitudes of professionals towards physical abuse 20 years ago.

It seems that those of us who have a responsibility for child care have a lot to learn about the sexual abuse of children and this book is a good place to begin. There are contributions on various aspects of the problem by 18 authors, most of them colleagues of the editors in Denver, Colorado, and the subject matter, which is based mainly on American experience and practice, is arranged in five parts: recognition, the law, psychodynamics, treatment, and prognosis. The sections on the British survey and on the medical management are perhaps the most helpful for British paediatricians. Because most of the contributors are American psychiatrists and social workers the style and language will be difficult for British medical readers to understand. However, with a little effort it should be possible to grasp the meaning of such phrases as ‘family disqualifier’ and ‘spouse subsystem’. Any book on child abuse with Henry Kempe’s name on the cover should be worth reading and this one is no exception.

A D M JACKSON

This was written by a senior registrar and a senior lecturer in paediatrics and they have tried to provide more than just an account of the care of normal babies without creating a textbook of neonatal intensive care. It was meant for junior medical staff as well as nurses and midwives taking advanced diplomas, and in general it fulfils its intentions.

The opening chapters discuss the challenge of perinatal care and prenatal influences on the baby, and are followed by chapters on resuscitation and care of normal babies. There is a series of chapters on particular problem areas—such as low birthweight babies, respiratory difficulties, nutrition, congenital malformations, birth trauma, jaundice, bleeding, neurological problems, and infection. Short chapters on the large-for-dates baby, the problems of coping with stillbirth, neonatal death, deformity, and handicap, and on perinatal care in developing countries complete the main text. Chapters are followed by suggestions for further reading and the appendix includes some normal values, standard drug doses, a list of addresses of well-known paediatric societies and associations, and two methods for assessing gestational age.

The book will help a junior paediatrician in a district general hospital to establish a baby on a ventilator and sustain it at least until the flying squad team arrives, but perhaps a too detailed account of intrauterine feeding and the insertion of a central venous line is given. On the other hand, tolazoline, a potentially hazardous drug, is mentioned in one sentence which gives precise dosage but does not mention side effects.

This fits into a doctor’s white coat pocket and contains many diagrams, graphs, tables, and black and white photographs, most of which show what they are supposed to show.
