Hypoplastic optic nerves and pituitary dysfunction

A spectrum of anatomical and endocrine abnormalities

R STANHOPE, M A PREECE, AND C G D BROOK
Department of Paediatrics, The Middlesex Hospital and The Institute of Child Health, Guilford Street, London

SUMMARY Fourteen children with optic nerve hypoplasia associated with either mid-brain abnormalities or pituitary dysfunction, or both, are described. All patients were either partially sighted or blind. One case is reported in detail. The importance of hypoglycaemia in the neonatal period and later in childhood is emphasised in relation to diagnosis and developmental delay. Pituitary dysfunction is variable and may be progressive. Forty percent of the patients had a septum pellucidum and its presence or absence cannot be used as a radiological marker for the condition. Long term endocrine follow up of these patients is required.

Congenital optic nerve hypoplasia is now more frequently recognised. The association of optic nerve hypoplasia and absence of the septum pellucidum was first described in 1941. In 1956 in a post mortem study, 36 cases of absence of the septum pellucidum, 9 of which had optic nerve hypoplasia, were described. The syndrome of septo-optic dysplasia, the name given by de Morsier to the association, implies an absent septum pellucidum. The endocrinopathy associated with septo-optic dysplasia in childhood has since been documented. have been described with a normal septum pellucidum. The diagnosis may only become apparent in adult life, but missing the diagnosis in childhood may have serious consequences because growth hormone deficiency and hypoglycaemia are not uncommon. This series is reported to draw attention to the features that should alert physicians to begin early treatment.

Patients

Case report (case 5). A girl weighing 3 kg was born by normal delivery after an unremarkable pregnancy. She had hypoglycaemia during the first days of life. At 2 months of age blindness was noticed and bilateral optic atrophy was diagnosed. Her developmental milestones were more delayed than would have been accounted for by her partial vision. Convulsions, occurring in the early morning before breakfast, started at the age of 8 years but treatment with sodium valproate did not reduce the seizure rate. Blood sugar was not measured during any seizure. Computed tomography (CT) showed a normal septum pellucidum.

At the age of 6 years her height was well below the third centile (Figure). Despite a low height velocity, no endocrine assessment was undertaken because a CT scan showed the presence of the septum pellucidum. At 14 years of age she was referred for assessment at the Middlesex Hospital. A high resolution CT scan showed hypoplastic optic nerves and chiasma; the pituitary gland and sella tureica were small. After intravenous insulin (0.15 U/kg) she had profound hypoglycaemia with inadequate cortisol and growth hormone responses. Although endocrine replacement treatment has now begun, the probable damage from her hypoglycaemia is irreversible and unfortunately, as she has signs of early puberty, her ultimate height will be very short.

This case with its unfortunate sequelae prompted a review of our experience of 14 patients with optic nerve hypoplasia and pituitary dysfunction. All patients had typical fundal changes of optic nerve hypoplasia, either unilateral or bilateral, as previously described. In addition they had an absent septum pellucidum or pituitary dysfunction, or both. The neurological and endocrinological data of the 14 patients are summarised in the Table. Patients 1 to 4 have been reported previously.

GH = Growth hormone; ACTH = Adrenocorticotrophin; TSH = Thyrotrophin; HGH = Human growth hormone; DDAVP = Desamino-d-arginine vasopressin; ITT = Insulin tolerance test.

Results

Eleven of the 14 patients were girls. Although blindness was always noticed in the first year of life, the average age at diagnosis was 5-4 years. In case 5, however, and despite neonatal symptoms the diagnosis was not made until age 14 years. Three patients had neonatal hypoglycaemic convulsions which recurred in later childhood. In none of these children did the hypoglycaemia point to an early diagnosis.

Of the 13 patients who had had neuroradiological studies, 7 had a normal septum pellucidum and in one additional patient the septum pellucidum was present in part. Eleven patients were below the 3rd centile for height at presentation. Only one was above the 25th centile, either at presentation or after treatment. Varying hypothalamo-pituitary dysfunction was found, from isolated defects to panhypopituitarism. Two patients (cases 1 and 11) had a progressive endocrine deficiency.

Discussion

The endocrine and anatomical associations of optic nerve hypoplasia have been described for more than a decade but we have seen four children recently (cases 5, 8, 12, and 14) in whom the diagnosis had been delayed unnecessarily. In cases 5, 9, and 12, the presence of the septum pellucidum was believed to exclude the endocrinopathy. This series has confirmed previous reports that the septum pellucidum is frequently present in 'septo-optic' dysplasia and the presence or absence of septum pellucidum gives no indication of the possible endocrine dysfunction. In two patients (cases 5 and 13) the characteristic appearance of optic nerve hypoplasia was mistaken for optic atrophy.

Although the midbrain lesion and visual impairment are present from birth, the endocrine abnormalities may evolve later in life. The retarded developmental progress that is characteristic of these children may be partly due to recurrent hypoglycaemia and partly to visual impairment. Late diagnosis may allow irreversible neuronal damage from hypoglycaemia as well as a reduction in final height. Pituitary dysfunction may present as neonatal hypoglycaemia and this should provide an additional clue to early diagnosis and treatment. No treatment is available to alleviate the visual defects, but recurrent hypoglycaemia and short stature are unnecessary additional handicaps.

We recommend that in patients with congenital blindness because of optic nerve hypoplasia, endocrine assessment should be mandatory, irrespective of the presence or absence of mid-brain lesions on neuroradiology. All such patients should be followed for life. An increased awareness of the association of hypoplastic optic nerves and pituitary dysfunction is required by both ophthalmologists and paediatricians if late diagnosis is to be avoided.

Addendum

In December 1983 a boy aged 11 weeks was referred to this hospital with intractable hypoglycaemia and a predominately conjugated hyperbilirubinaemia. Fundoscopy showed hypoplasia of the right optic disc and high resolution computed tomography showed unilateral optic nerve and pituitary hypoplasia with an intact septum pellucidum. The baby has growth hormone, adrenocorticotrophic hormone, and thyroid stimulating hormone deficiencies.
