Incidence of normal micturition in myelomeningocele

and, perhaps, a few with pure meningoceles rather than myelomeningoceles.

Our findings have prognostic implications. Neonatally it is impossible to be certain of sacral motor sparing but conus reflexes are readily demonstrated and so also is sensory sparing by general arousal to perianal pinprick. No matter how slight the neurological deficit otherwise, neuropathic bladder is virtually certain in an infant with negative conus reflexes or a sensory complete cord lesion. By contrast, one with a combination of positive conus reflexes and a sensory incomplete cord lesion may ultimately prove to have normal bladder and bowel control.

Treatment of refractory ulcerative oesophagitis with omeprazole

A M Dalzell, J W Searle, M K Patrick

Abstract

A 7 year old boy with ulcerative oesophagitis failed to respond to a two month course of intensive medical treatment using H2 receptor antagonist treatment in combination with domperidone and sucralfate. He demonstrated complete resolution using omeprazole 10 mg once a day for eight weeks.

The aetiology of reflux oesophagitis is multifactorial. However, patients do have more frequent reflux episodes and poorer oesophageal acid clearance than normal individuals.1 Conventional medical management of oesophagitis in childhood is based on positioning and the use of pharmacological agents including H2 receptor antagonist treatment. Although the usual clinical outcome is effective resolution of symptoms, a proportion of patients with severe oesophagitis fail to respond. Omeprazole as an alternative treatment to H2 receptor antagonists has been extensively reported in adults with ulcerative oesophagitis and peptic ulcer disease,2 but not in children.

Case report

A 7 year old boy presented with vomiting associated with postprandial colicky abdominal pain and a weight loss of 4 kg in the preceding six weeks. There was a history of effortless vomiting from birth, which had not previously been investigated. Despite this, growth parameters were appropriate for age: weight 23-5 kg (50th centile), height 119-5 cm (50th centile), and clinical examination was unremarkable but for borborygmi and non-specific abdominal discomfort.

A blood film suggested a mild iron deficiency anaemia with a haemoglobin concentration of 108 g/l, mean corpuscular volume 68 fl (normal range 7-95) and mean corpuscular haemoglobin 23 pg (25-30). Abdominal ultrasound and a barium meal and follow through were normal. Liver function tests, serum electrolyte concentrations, amylase and lipase, and urine and faeces microscopy and culture were also normal. Oesophageal manometry was not performed.

Upper Gastrointestinal Endoscopy

Upper gastrointestinal endoscopy showed circumferential ulceration and exudate in the lower third of the oesophagus. The stomach and duodenum were normal. The symptoms and oesophageal appearance did not resolve with a 12 week course of ranitidine (75 mg twice a day), together with domperidone (10 mg three times a day), and sucralfate (500 mg twice a day) (fig 1a). Omeprazole 10 mg once a day was...
started, and the patient gained symptomatic relief within three days, and demonstrated progressive weight gain. The abnormal endoscopic findings had resolved after eight weeks of treatment (fig 1b). At follow up one year later the child was asymptomatic.

**HISTOLOGY**

Histology of biopsy samples taken before the commencement of omeprazole treatment showed extensive ulceration with mixed fibrinous and inflammatory cell exudate covering a granulation base (fig 2a). Histology from biopsy samples taken after eight weeks of omeprazole treatment showed structurally normal oesophageal lining epithelium into which there was migration of only very occasional leucocytes (fig 2b).

**Discussion**

We have documented ulcerative oesophagitis in a 7 year old boy with significant gastrooesophageal reflux. Treatment with an H₂ receptor antagonist in combination with a promotility agent and mucosal protective agent for eight weeks failed to produce any improvement. The hydrogen-potassium ATPase proton pump inhibitor, omeprazole, produced symptomatic relief within three days and effective resolution of the oesophageal lesion after eight weeks of treatment. While there is no published experience of omeprazole use in children, it is the treatment of choice for severe oesophageal ulcerative disease in adults, and is more effective in treating reflux oesophagitis than H₂ receptor antagonist therapy. It has been used safely at doses in excess of 60 mg/day for three years or more in patients with Zollinger-Ellison syndrome.

Long term treatment using omeprazole is uncharted territory. While there will always be a place for surgery in severe gastro-oesophageal reflux disease, with or without oesophagitis or stricture, we suggest that omeprazole should be considered as alternative treatment for children with ulcerative oesophagitis resistant to traditional therapy.
