Primary antiphospholipid syndrome presenting as complicated Henoch–Schönlein purpura

K Monastiri, H Selmi, B Tabarki, M Yacoub, T Mahjoub, A S Essoussi

A child showing signs of Henoch–Schönlein purpura developed a right tibiofibular vascular thrombosis. Antiphospholipid antibody tests were positive for both lupus anticoagulant and anticardiolipin antibodies. This suggests that an antiphospholipid syndrome should be considered in cases of Henoch–Schönlein purpura and antiphospholipid antibodies should be measured to determine whether prophylactic antithrombotic measures are needed to prevent thrombotic manifestations.

The antiphospholipid syndrome is a thrombotic disorder characterised by recurrent arterial or venous thrombosis or recurrent pregnancy loss and the presence of circulating antibodies directed against phospholipids. Antiphospholipid antibodies have been associated with antiphospholipid syndrome during four years of follow up. Antiphospholipid syndrome in paediatric patients has a wide clinical spectrum ranging from benign signs such as migraine or livido reticularis to a “catastrophic” occlusion syndrome. It is usually primary, but sometimes associated with systemic disorders such as systemic lupus erythematosus. Our patient experienced purpura, abdominal pain with bloody diarrhoea, and joint and kidney involvement. These signs fulfilled the American College of Rheumatology 1990 criteria for Henoch–Schönlein purpura.

CASE REPORT

A 6 year old boy was admitted to hospital with a diagnosis of Henoch–Schönlein purpura. He had no previous medical problems including renal or neurological diseases, and had no family history of connective tissue disorders. Two days before admission, he developed extensive purpuric lesions of both legs, arthralgies (especially of knees and ankles), and abdominal pain. On examination he appeared to be well but had a mild fever (38°C); blood pressure was 110/60 mm Hg. He had extensive purpuric lesions of both legs. Oropharyngeal, heart, and lung examinations were normal. Abdominal examination revealed diffuse tenderness and the limbs were normal except for knee and ankle arthralgies. Urinalysis showed mild haematuria and proteinuria. Five days later, he developed left orchitis, livedo reticularis, and no systemic lupus erythematosus features; all symptoms resolved after anticoagulant therapy.

DISCUSSION

Antiphospholipid syndrome in paediatric patients has a wide clinical spectrum ranging from benign signs such as migraine or livido reticularis to a “catastrophic” occlusion syndrome. It is usually primary, but sometimes associated with systemic disorders such as systemic lupus erythematosus. Our patient experienced purpura, abdominal pain with bloody diarrhoea, and joint and kidney involvement. These signs fulfilled the American College of Rheumatology 1990 criteria for Henoch–Schönlein purpura. Subsequent arterial and venous occlusions proved to be caused by a primary antiphospholipid syndrome; multisytemic manifestations purpura, vasculocclusive manifestations with high anticardiolipin antibodies and no systemic lupus erythematosus features; all symptoms resolved after anticoagulant therapy.

Antiphospholipid antibodies have been associated with vasculitic disease such as Henoch–Schönlein purpura but...
without any pathogenic events of antiphospholipid syndrome. Garber et al reported an adult case of Henoch-Schönlein purpura associated with anti-Ro (SSA) and antiphospholipid syndrome with recurrent deep vein thrombosis. Sokol et al reported a case of a 15 year old girl who had features of Henoch-Schönlein purpura and stroke, with transient IgA antiphosphatidylethanolamine antibody in her serum and CSF.

Henoch-Schönlein purpura and antiphospholipid syndrome are multisystem diseases which may affect the skin, joints, gastrointestinal tract, kidneys, brain, testes, myocardium, and lungs.

The pathogenetic mechanisms underlying Henoch-Schönlein purpura are still poorly understood. However, IgA abnormalities suggest an immunological basis. Antiphospholipid syndrome also has an immunological basis related to antiphospholipid antibodies and/or phospholipid binding proteins. The question remains whether it is a coincidental association or the same disease with different manifestations.
