We regard pH monitoring in children who have experienced an ALTE but have no clinical pointers to GORD as being of little value, and contend that there is no evidence base for such an approach.

**Authors’ reply**

We appreciate the thoughtful comments on our recent paper. The main points raised by Dr Puntis and Booth are:

- Most of the studies in this review did not diagnose GORD by the accepted criteria
- The issue of causality was not addressed
- They recommend investigating for GORD only when there is corroborating clinical information because occult reflux does not cause apnoea.

We agree that the diagnosis of GORD disease requires a combination of clinical information and selective testing. We acknowledged in our paper that there were varying investigative protocols for this disease. We were unable to review the diagnostic criteria for all studies. This reflects the lack of one standardised, well validated test. pH probes have limitations as well because they do not detect non-acid reflux. The clinicians in the studies reviewed reported GORD as a diagnosis after an ALTE, but did not say it caused the ALTE.

The issue of causality was clearly addressed in the discussion and we agree that it is very important for exactly the reasons which Drs Puntis and Booth highlight. To repeat, we did not recommend undertaking pH monitoring. Instead, when there is a clear temporal relation with an ALTE, we suggest pH monitoring.

Replacing mercury sphygmomanometer in paediatric clinical practice: is there a need for a consensus conference?

The definition of normal blood pressure (BP) values in adults and children is based on mercury sphygmomanometry, and standard mercury readings are the main basis for BP disease associations. Unfortunately, mercury has toxic effects on the environment and the mercury sphygmomanometer will have to be gradually replaced. However, there is a rearguard movement to retain mercury until some satisfactory substitute can be found.

We investigated the type of BP devices that are currently being used in Departments of Paediatrics in Greece. In a total of 76 departments, 30% use a mercury sphygmomanometer, 25% use automated devices, 25% use either mercury or automated devices, and 20% use an aneroid sphygmomanometer. Interestingly, in 1 in 3 departments has the commonly used automated monitor “Dinamap” (several models); furthermore, half of these departments are using the model 8100. However, the accuracy of Dinamap monitors is questionable, especially the model 8100, which, when tested against the standard mercury sphygmomanometer, was found to detect mean systolic and diastolic BP values significantly above the cut-out readings.

We feel that replacement of mercury sphygmomanometer with automated devices has become increasingly common but, also, rather questionable in some countries, considering the lack of validated automated devices for the paediatric age group. The recent “International Protocol” established by the European Society of Hypertension for validation of BP measuring devices, is designed for adults and does not make recommendations for children. Facing the beginning of a new standard in clinical sphygmomanometry, there is little doubt that we need a consensus conference. Such a conference would help in making recommendations for endorsing the use of alternative devices as the optimal replacement for mercury devices. Moreover, the development of appropriate validation standards for paediatric use of BP devices and the elimination of inaccurate monitors would improve our methods of BP measurement and interpretation.

Chief complaints in pediatrics

Edited by Theodore C. Sectish.
PocketMedicine.com, 2002. US$50.00. Buy from: http://www.skyscape.com. Memory requirements: for palm 0.4 MB, for Pocket PC 0.8 MB.

Have you ever wondered, looking at Wisteria, if the plant in front of you is right or left winded? Do you know how to tell? Once you know, it is easy. It is just the same with this publication. This is not a book, not even an eBook. Chief complaints in pediatrics is software. It is worth clarifying this right at the start, as there are some practical consequences to this. After installation you will find its icon in the list of programs. If you simply follow the prompts, it will install itself to the main memory. If you then realise that you want to have it on your memory card you will have to go through uninstall and install (to the chosen location) procedure. As this is not a book, there are no numbered pages.

The interface is easy and intuitive, you will be able to do it all without looking into Help. The same unified interface can be found on all Skyscape products; if you have used any popular free program, for example a word processor, that works like an extended medical calculator, you will find the familiar interface of Skyscape in this program. Chief complaints in pediatrics comes with an internal link to other Skyscape products that are already installed on your PDA.

The display is tidy: menu choices on the top, along the right side, and on the bottom of the screen, and text in the middle. The icon for the program is on the page itself, main index, table of contents (with alphabetical list of topics), history (analogous to the same feature in Internet Explorer), links (to other Skyscape products on your device), and toggling arrows. There are also arrows to navigate back and forward within the text of the program, and a little pen which is an icon to tap if you want to add notes to the topic (and this includes the option of adding other topics). The menu at the bottom of the page is to edit (make annotation and bookmarks), view (change font size and access the Main index), tools, and help.

A pleasant feature of this software is the use of voice note. The text is also likely to appeal to junior doctors embarking on a paediatric career who require refreshment of how children present when ill. The 40 presentations of unwell children that the book describes are likely to incorporate many such patients who will present to a department.

L J Phillips

Pediatric physical diagnosis electronic atlas

Today, medical education faces huge challenges. The patient contact time essential for developing clinical acumen has been progressively eroded by increased trainee numbers, reduced working time, reduced training duration, shifts, and encroachment of non-medical professional and other non-medical areas. Skills labs have evolved to cover basic skill sequences, but there remains a gap between core skills and clinical practice. An obvious approach is to “can the experience” using modern information and technology to bridge the hiatus, ensuring some exposure at least to core conditions. There are various ways of developing such collections: the proprietary way, as here, or by using the internet, as for example at www.brisb.end.ac.uk/bbb, www.hon.ch/HONmedia, www.healthcentral.org, or www.peir.org. This single DVD comes in a large glossy box with significant dead space. The authors are American, mainly from the Children’s Hospital of Pittsburgh. The resource consists of “over 2500 visual representations of a broad range of common and uncommon pediatric disorders”. There are over 40 video and audio clips too. The images can be saved to a separate area (like a shopping trolley on the web), then transferred to PowerPoint. The video and audio can be navigated to on the disc and transferred using cut-and-paste. The license does not allow materials to be integrated into other teaching resources (for example, question banks), nor can the PowerPoint presentations be placed on the web or intranet. Images can be viewed without annotation, but there is no interactive self-assessment (that is, scoring or review of wrong answers).

The text “physical diagnosis” is used broadly, and is not restricted to clinical signs. For example, x-ray pictures, blood films, karyotypes, and diagrams are all included. It includes many normal children, for example in the section on child development. The resource quality is generally good to excellent, with most images presented as full colour JPs. The highlights for me were the video clips of different forms of epilepsy. These bring to life an otherwise difficult topic. I was a little disappointed with the quality of some of the heart sounds. Coverage is inevitably incomplete: for example, there were excellent radiographs of pneumocystis, mycoplasma, and tuberculous pneumonias, but none of typical lobar pneumonias or bronchiolitis.

Searching is rudimentary, either by one of 23 chapter headings and scrolling through the thumbnails or by using a simple search string (US spellings) through the annotations. There is no metadata, but audio/video files can be accessed separately using tabs. This means that there is a learning curve associated with using the resource effectively, with the potential to miss media that are in it. With repeated use its value increases greatly.

It is an excellent and reasonably comprehensive resource for an paediatric trainee to have available for teaching purposes, particularly those with slow or difficult internet access. A huge amount of work has gone into its production and the authors are to be congratulated. It provides a good way to learn most classical presentations for examinations, particularly DCH and Part 2, though the text version may allow for a more structured approach. I shall certainly be using it for my own teaching. I suspect that the restrictions of DVD capacity, publishing cycle (versioning), searching, and copyright will prove to be long term disadvantages compared with the web based approach. It is worth remembering that, while multimedia are useful they are no substitute for the “real thing”. The clinical experience engages the whole brain at sensory, intellectual, cerebellar, and emotional levels. We are still far from virtual reality here, but this resource is certainly an advance on a traditional textbook with text and few illustrations.

E Posner

The treatment of gait problems in cerebral palsy

I settled down to read this book, thinking it would be instructive and enjoyable—and I was not disappointed. Basic principles are clearly explained in the text and are well illustrated with appropriate clinical examples and case studies, supplemented by the CD-ROM.
Jim Gage is a master in the use of automated gait analysis to rationalise surgical decision making for children with walking disorders, and, with his wealth of experience, accumulated over more than 20 years, is a very appropriate editor for this volume. The clarity of his own thought processes is evident in his explanation of biomechanical principles applied to the complex dynamic gait problems encountered in children with cerebral palsy. A particular highlight is his chapter on the biomechanics of normal gait. His fellow contributors are all acknowledged experts in their own fields and complement his contributions well.

The main focus is the correction of problems with gait and the text illustrates how gait analysis can provide clear insight into the safety and efficacy of potential surgical intervention. The book is divided into five sections. Early chapters cover the neuroanatomical, neurophysiological, and biomechanical background; further sections are devoted to patient assessment, gait pathology, and treatment options including detailed discussion of orthopaedic surgery, and assessment of outcome. The role of the multi-disciplinary team is emphasised, and the kinematics and kinesiology of gait together with biomechanical modelling are covered in detail (and here the reader may just start to feel a little insecure in his knowledge of mathematics!).

The chapters on treatment demonstrate the logical differentiation between the primary, fixed problem—that is, the neurological injury itself; the secondary biomechanical problems, resulting from abnormal growth forces, which are amenable to treatment; and the tertiary compensatory problems which do not require treatment per se. Patterns of gait pathology are discussed with specific attention to hemiplegia, quadriplegia, and crouch gait, and the respective surgical solutions. Illustrative case studies are included and the data on the CD-ROM facilitates correlation between the clinical picture and the kinematic plots. The treatment role in corrective dorsal rhizotomy is carefully delineated. One chapter is devoted to non-operative treatment modalities including botulinum toxin and intrathecal baclofen. Perhaps the section on botulinum toxin for spastics has been expanded in the light of its increasing popularity as a first line treatment for reduction of dynamic spasticity—I was a little disappointed that it received only a passing mention in the treatment of upper limb deformities in hemiplegia, although there was more discussion of its use in the lower limb.

Although not all of us have access to a gait laboratory—and indeed it would not be appropriate to project all our patients with gait disorders to complex gait analysis—clinical gait analysis is readily performed in most centres treating children with spasticity. Basic biomechanical principles are equally valid across the spectrum of gait analysis, whether planning botulinum toxin injections or multi-level orthopaedic surgery. This book ably expounds these principles and illustrates their application to specific case studies, representing our experience with the most frequently encountered patient scenarios in clinical practice. The biomechanical rationale for the proposed treatment is explained, and the results are demonstrated from follow up studies. As such it has a guide to refer to as he follows his own, sometimes uncharted, course. I suspect that I shall be dipping into it many times to refresh myself of the finer details as I manage the children in my own clinical practice.

I thoroughly recommend it to anyone with even a superficial interest in the field, but beware, you may find yourself more involved as a result!

R J Jefferson

Minor trauma in children, a pocket guide

For many paediatric doctors the emergency department (aka A&E) is only visited when referrals are made, or the crash bleep summons its screeching sirens. These visits are usually straightforward, especially if the APLS creed can be chanted. However, for those of us who missed the emergency department in a rotation, the intricate management of minor cuts and bruises may evade us. Davies’s guide to minor trauma will help to glue the gaps in knowledge. From the initial child’s drawing on the front cover, there are a number of helpful illustrations, photographs, and x ray pictures that aid the guide and its reader. The presentation of the text leads your eyes through the various subheadings; important ideas are highlighted with the use of miniature road signs that are supposed to elicit an emergency stop.

The first few chapters set minor trauma in its context and do a good job of laying the ground work of management. Despite recent opposition to the use of such terminology, the reader is offered several interesting statistics on accidents and the outline of how strategies in society can prevent and assess trauma and management is given its rightfully prominent position as the foundation for good holistic care of the child. An overview of general wound and soft tissue management follows before the guide leads the reader through chapters exploring various locations of the body. Each chapter carries a concise description of the various minor injuries that can affect the area, accompanied by useful x ray pictures; ploughing through lengthy radiology and orthopaedic texts may now be circumvented.

More specific injuries such as minor burns are covered before reaching chapters that explore the difficulties of frontline medicine that have recently been exposed by the continued media interest in child protection. The chapter on non-accidental injury is regularly signposted with danger points. Davies makes one profound statement of the most difficult decisions that will resonate with many doctors, “You could be forgiven for thinking that paediatricians are perhaps obsessed by the subject but the reality is that delay in diagnosis is still common, the diagnosis itself can be extremely difficult to make, and the repercussions of either a ‘false negative’ or ‘false positive’ can be very damaging.” The following chapter helps explain the forensic and medicolegal aspects of assessing children with suspicious injuries, or those that might require personal presence in a court of law.

The final chapter looks at practical procedures. Most of us know how to negotiate the examination of the ear, nose, and throat, but how do you tie a sling? If your first aid is a little rusty, then help is at hand in the form of a “Blue Peter” solution with a paperclip and sticky-backed plasters. Overall the guide is a useful, concise aid to managing minor trauma, and would be a valuable reference for any emergency department. It collects together wisdom on the assessment and management of problems not easy to obtain elsewhere; apart from from the experienced casualty nurse.

S Fountain-Polly

The Chailey approach to postural management, 2nd edition
Edited by Teresa E Pountney, Catherine M Mulchahy, Sandy M Clarke, Elizabeth M Green. Chailey Heritage Clinical Services, 2004, £30.00, pp 194. ISBN 0954825802

Disorders of posture are a frequent feature of neurological disability. These often limit a child’s ability to function efficiently and access his/her environment. They also tend to progress in time with a potential for further loss of abilities, orthopaedic complications (such as scoliosis and hip dislocation), and secondary pain. Therefore professionals who work with these children find themselves constantly battling to maintain and, if possible, correct these abnormal postures. I often find myself in the situation of having to recommend interventions or prescribe expensive and sometimes cumbersome postural equipment for which only little evidence of efficacy is to be found in the medical literature. I was therefore looking forward to reading The Chailey approach to postural management in which I hoped to find some answers to my predicaments.

This book presents the approach developed over 20 years of research and clinical practice at the Chailey Heritage Clinical Services, a centre that has acquired national recognition in the management of children with complex physical disabilities. It progressively brings the reader to understand the principles of assessment and how to solve postural problems. The pedagogic style is very much that of a training manual, with multiple questions and activities targeted at the reader, and it was no surprise to learn that Active Design Ltd (the company who manufacture the postural equipment described in this book) run courses using this volume as their reference material. The theoretical basis that underpins the approach is concisely but clearly described in a series of chapters on the relevant aspects of biomechanics, neuromuscular, motor control, and motor learning theories. The book is well referenced and the text is supported by a number of excellent illustrations.

The management programme per se relies mainly on the 24 hour provision of postural
Cerebral palsy, principles and management

We devote time and energy, disproportionate to their numbers but not to their need, to these children. Diagnosis is often difficult, may be delayed, and the physical and psychological problems, intractable. There is an enormous and fast growing literature to help us, had we time to access it. A well organised, clear and concise introduction to the conditions which fall under the heading of cerebral palsy, and an update on management of the difficulties which come with it, would be welcome.

Unfortunately, Cerebral palsy, principles and management, does not fill the bill. As I read, I felt like a diver, struggling deeper into a hole. There seemed to have surfaced with some pearls, but aware that there would be few, if any, to take home, and increasingly frightened of drowning.

The most striking obstacle is the language. A substantial portion of the book reads as if mechanically translated by a computer unfamiliar with conventional English medical phrases. So there are such novelties as EPH-gestosis, superior and inferior kinetic neurophysiological insults, atrophic cerebral palsy, and stimulation buttons on the tooth vestibule or the palate plates. I liked the idea of suspicious newborns, but was less happy to read about non-functional children. And when it came to the “batrachoidal state of the trunk”, I began to wonder if I had carelessly strayed into a botany or zoology text. So there are some problems with reading and writing. The arithmetic is not too hot either—I was surprised to be told that “there have been more than 200 years since the first description of cerebral palsy made by Little in 1843”. How time flies!

Twenty four authors contributed. The editors could hardly have been light, and there is considerable repetition of information between, and sometimes even within, chapters. Misprints abound. Some illustrations are of poor definition, duplicated, or reversed, and their relevance is not always obvious. Legends are not always accurate. One of the tables is in three languages. Of the 131 references in the bibliography to the first chapter, only 104 are referred to in the text. Conversely, 10 references in the text have no corresponding entry in the bibliography.

Feeling despondent, I checked the 12 references to published papers by Little—all were inaccurate and one paper (admittedly the best known) appeared twice.

No doubt form is less important than substance. But it was not just the distractions of form that made it impossible in all but a very few chapters to shell out a pearl. I was unable to decipher the meaning of considerable portions of the book. There is undesirable grit as well—controversial advice regarding anticonvulsants, annual pertussis immunisation, and treatment of undescended testicles by hormone injection in preference to orchidopexy, to take three random examples. And any candidate for MRCPPCH who holds a baby upside down by one leg to test the Collis II reaction as depicted in the chapter on therapeutic concepts, is likely to fail. Another child on the same page appears to be being smothered beneath an ample bosom. I cannot recommend this book.

M Wheeler

Management of the motor disorders of children with cerebral palsy, 2nd edition

There has been an interval of 20 years since publication of the first edition of this book, and this second edition reflects the progress in this field. David Scrutton has invited two colleagues, Dianne Damiano from the USA, and Margaret Mayston, originally from Australia to join him as editors, and together they have commissioned contributions from an international group of experts who reflect the current approach to care. The book is written primarily for therapists but there is much of value for paediatricians.

The introduction describes current treatment dilemmas. In the past, physiotherapy programmes were based on philosophies of care. Modern management is based on clinical principles with a scientific rationale for their use. Evidence for their efficacy is emerging but remains sparse.

The first chapter defines cerebral palsy and describes the various cerebral palsy syndromes, their correlation with MRI scan findings, and the concept of causal pathways. A wide range of descriptive terminology for cerebral palsy still exists which results in confusion, and more emphasis on areas of agreement would have been useful, such as that reached by collaboration between cerebral palsy registers.

The broad principles of care are well covered. Peter Rosenbaum has written an excellent chapter on the benefits of family centred care, involving the extended family such as grandparents. The evidence shows that this is associated with greater satisfaction with care and better outcomes, and is most important for children with complex disability and multiple problems, where the risk of fragmentation of care is high. He then persuasively argues that developing opportunities for involvement of carers in promoting participation and achievement of functional goals, rather than fixing impairments. Eva Bower and Roslyn Boyd follow with helpful practical guidance to therapists on goal setting, models of assessment, and reliable tools to measure change or outcome. It is made clear that goals differ from aims, they should be specific and measurable, and relate to problems experienced by the child.

The second half of the book is devoted to therapeutic possibilities. At the cerebral level, some existing possibilities are emerging based on neural plasticity in the damaged nervous system, such as constraint induced therapy. The reader is reminded that abnormal muscle tone is only one feature of the motor syndrome in cerebral palsy, and other aspects, such as muscle weakness, may be successfully treated with strengthening exercises. There has been an explosion of interest in new treatments for spasticity, such as intrathecal baclofen and focal injections with botulinum toxin. In controlled trials to date, functional gains have been limited and overall muscle tone can be reduced by simple measures, such as relieving pain or ensuring a good night’s sleep.

The orthopaedic contribution emphasises the progressive nature of the musculoskeletal disorder in cerebral palsy and how this confuses families who learn that cerebral palsy is due to a static cerebral lesion. A biological clock is ticking and unrelieved muscle spasm gradually leads to muscle shortening, bony torsion, joint instability, and ultimately degenerative arthritis. Appropriate management could have a major influence on the natural history. For example, monitoring of the hips in bilateral cerebral palsy with early intervention reduces the risk of dislocation and painful arthritis in adulthood. A chapter is devoted to the conservative management of deformity, using 24 hour postural care in conjunction with strategies to facilitate movement and function.

The Wealth of alternative therapies and approaches to care, combined with a lack of hard evidence to promote one above the other, has been confusing for parents as well as professionals, and Margaret Mayston’s contribution is helpful for both. She describes the various treatment approaches, ranging from the Bobath technique to alternative or complementary therapies such as hyperbaric oxygen, giving a balanced view of the available evidence as to their merits and disadvantages.

With the increasing lifespan of the most severely impaired young people, the focus on cerebral palsy in adults and should be essential reading for the paediatric team. There is evidence of a gradual loss of function and independence, aggravated by increasing weight and loss of mobility. Adult care is best fragmented, and a case is made for a coordinated service for adults.
Paediatric oncology, 3rd edition

The first thing that struck me as a newcomer to this 3rd edition of Paediatric oncology is the heavy alliteration of title and editors. The news was that exactly the book I have been looking for—both to have with me in the clinic and on the ward, and to dip into at night. It is a good size: heavy enough to promise sufficiently detailed to be of real use, and yet light enough to be carried in the hand. The paper is pleasingly thick, so that the print is easily legible, and both the black and white photographs and the colour plates are very clear. As a haematologist, I could have wished for a little more morphology, but overall the balance between picture and print is good. The layout makes the chapters readable, and even the sections which looked rather daunting with prose running in unbroken paragraphs over several columns were in practice simple to read.

The content is broken up into five parts: Scientific and diagnostic principles; Diagnosis and management of individual cancers; Advances in therapy: megatherapy; Advances in therapy: targeted therapy; and Late effects and supportive care. Each part is then divided into appropriate chapters. I particularly liked the use of boxes at the end of each chapter to recap key points. The reference lists are extensive and helpful in pointing to significant papers.

The text and the references have all been updated, and, given the length of time needed to get such a tome to press, are reasonably current. The list of contributors represents recognised experts in the various fields, and is drawn predominantly from the United Kingdom, making this a very relevant book for clinical practice here. However, I found myself wondering on acute leukaemia a little disappointing. I felt the discussion rather overlooked the UKALL trials, concentrating instead on other protocols, and in particular the ALL-BFM trials—reflecting the author’s own experience. This is, of course, relevant and of interest, but, given that this is the most common childhood malignancy, and that this book is presumably aimed predominantly at a British audience, seemed to be a significant weakness.

This book is already a standard on the shelf of paediatric oncologists and haematologists. Would I recommend it for a general paediatrician or a haematologist working in a district general hospital? Yes, definitely. Is it worth upgrading from the last edition? Again, yes—for two reasons: firstly, this is a rapidly changing field, and the old edition is now out of date; and secondly, the quality of this edition, especially the photographs, makes it a delight to read.

S M Wallis

Pediatric orthopaedics and sports medicine, the requisites in pediatrics

This is the first of a series on paediatric sub-specialties.

My first impression of the book was that the content was daunting for a paediatrician. However, after reading selected chapters in detail, the authors certainly fulfilled their aim to educate paediatricians on how to approach an orthopaedic problem. My experience in paediatric training is that there is little exposure in managing musculoskeletal problems. The development of the musculoskeletal system in childhood and adolescence is a very important aspect of paediatrics and tends to be a neglected part of paediatric training. This book will help to rectify this.

There is substantial detail describing the mechanism and management of injuries. In fact, a patient of mine brought in her child who had fractured her radius and ulna. She had consulted an orthopaedic surgeon but requested a second opinion from me. With the help of this book, which happened to be on my desk at the time, I was able to give an informed opinion on the appropriate management of this problem. I made no apologies about using the book!!

Sports medicine includes how the body adapts to exercise and the effects that exercise has on medical conditions such as asthma, diabetes, obesity, sports injury, malignancy, and other chronic disorders of childhood. Included in this, is the use of exercise in managing these conditions. Medical conditions were not included in this book. Thus a better title of the book would have been “Pediatric orthopaedics and overuse injuries in childhood and adolescence”.

The book gave detailed accounts of overuse injuries involving anatomical sites. However, I felt that there could have been an introductory section describing, in principle, the unique types of injuries in childhood and adolescence. A more detailed account of the rehabilitation of injuries, for example, the role of physiotherapy and biokinetics would have been helpful.

The chapters on paediatric rheumatology were clear, detailed, systematic, and moreover easy to read.

The layout, tables, and photographs were excellent. The blocks summarising the salient points of each chapter were very useful. Above all, each section was well referenced.

This book is highly recommended to paediatricians and health professionals working with children.

R Leaver

Childhood epilepsy: language, learning and behavioural complications

Given that Alexander the Great, Julius Caesar, Cardinal Richelieu, and Lenin all suffered from epilepsy it is clear that epilepsy does not preclude future career success. The prominence of sufferers within the higher echelons of the creative arts is striking. Dostoevsky, Flaubert, Moliere, and Byron are just a handful of names that immediately spring to mind. Van Gogh’s most creative period coincided with the time when his epilepsy was at its worst. And yet, we know that epilepsy can have a dramatic and disastrous effect on the cognitive and language abilities of our paediatric patients. It is hard not to be moved by West’s description of how his son regressed following the development of infantile spasms. We hear similar stories time and again in paediatric clinics of how an apparently normal baby arrests developmentally and then regresses coincident with the onset of infantile seizures.

It must be equally distressing to be the parent of a child with Landau-Kleffner syndrome (LKS). One day you have a previously chatty 3 year old who suddenly is unable to understand what you are saying to him. Their speech and behaviour deteriorates and, to cap it all, they develop seizures. We do not understand the relation between epilepsy and the cognitive, behavioural, and linguistic disorders and epileptic syndromes. The book gives detailed accounts of other paediatric epilepsy syndromes. In both LKS and West’s syndrome they may have chaotic status-like electroencephalograms. We postulate that such chaos must be interfering the formation of critical neural synapses and pathways. However, the resolution of such electrographic disorder and clinical seizures may not, unfortunately, coincide with any cognitive or language improvement.

We search for effective treatments for these disorders. The breadth of different treatments used suggests that we are uncertain where to target our therapeutic approaches. For example, in LKS, steroid treatment is often of little benefit. The situation, but is it because they are modifying some infectious or autoimmune process or through their action at the GABA-A receptor? Indeed our treatments may exacerbate the situation. Virtually all the anticonvulsant drugs have been associated with behavioural and cognitive problems.

Of course, I am exaggerating the state of confusion in this area… but only slightly. I turned to Professor Svoboda’s book on the subject, looking for some clarity and direction. It is a veritable goldmine of anecdote and case reports. A lifetime of reading and clinical experience are condensed here. It would be wrong to say that this is an evidence-free area. Svoboda documents a wealth of studies, references, and data.
However, at the end of the book I longed for some critical appraisal of the evidence he had marshalled together. He gives no indication, for example, of the relative benefits of steroids, immunoglobulins, anticonvulsants, and sub-pial transection in the treatment of LKS.

In fact, this book is a testament to the lack of knowledge that exists. There is a pressing need for a good evidence base about the actiology and treatment of these disorders. Which treatments improve cognitive outcome in infantile spasms? Is surgery preferable to medical therapy in LKS? Does treatment alter the prognosis of so-called benign focal epilepsies of childhood? The answers to such questions need to be unearthed but they are not to be found or hinted at in this book.

F J O’Callaghan

PediSuite 5.0

PediSuite is produced by Medical Wizards, a company founded in 2000 by a practising physician. The program is large and consists of 15 modules. Within each module there are numerous options. The selection of calculations, regimes and protocols is huge. Getting to know the content is time well spent as the information that you will be looking for you would usually want to know quickly.

This is software that aims to be a powerful calculator rather than an information source. Consequently, most of the modules contain some basic information about the topic but “the meat” of the program is numerous calculators that instantly work out dosages, speed of infusion, body mass index, crew score, etc for a given child. The interface is fairly intuitive and once you know what it contains no further guidance is required to be able to use it proficiently. There is one point where I stumbled and for some time thought that the program was freezing the PDA: where I stumbled and for some time thought that the program was freezing the PDA.

The more I used this software the more impressed I was, finding more and more useful tools. PediSuite is the most useful PDA program for a paediatric doctor I have come across. It is an extremely powerful tool for any paediatrician and it can be recommended at any stage of their career.

E Posner

Safeguards for young minds: young people and protective legislation, 2nd edn

Edited by Richard White, Anthony Harbour, Richard Williams, Gaskell (The Royal College of Psychiatrists), 2004, £15.00, pp 118. ISBN 1 904671 02 0

This book is invaluable for child psychiatrists, but not all paediatricians would be so attracted to it, except those who wish to understand the legal basis of child protection work. Those who might see it as irrelevant would be missing out on the combined rich experience of two paediatric solicitors and one child psychiatrist.

The chapter on consent is essential for all clinicians dealing with children, and has a superbly helpful flow diagram detailing how and when the child, young person, or parents can agree or refuse to medical or psychiatric assessment or treatment. The rules governing consent and refusal are surprisingly different.

To my consternation, it leaves out all mention of assent, which I understand is a young person’s agreement to something that is legally sanctioned by others, and which I think is increasingly being sought in written form.

The best advice in the book is contained in one of the prefatory pages—consult a solicitor whenever in doubt. Don’t leave it until the issue is so contentious as to need deciding by the Courts. If you can develop a relationship with a legal adviser, this, the authors say, will be more valuable than any book. Although this may appear to be a free advert for solicitors, it is sound advice: your professional indemnity association and your Trust’s solicitors should already be paid for.

This is the second edition of a 1996 book that expanded on the authors’ condensation (in previous writings) of The Children Act 1989 to include related legislation. The new edition includes explanations for professionals dealing with children of The Human Rights Act 1998, The Children (Leaving Care) Act 2000, and The Mental Health Act 1983, revised in 1998 by a new Code of Practice. It will need further updating when and if the intended new Mental Health Act becomes law. The authors tread with great clarity through the confusing overlap of the Children Act and the existing Mental Health Act—which should be clarified by the new Act. They cover what you can and can’t do to children in hospital, and how age and the Gillick principle should affect clinicians’ decisions.

The book is written in commendably clear language, with a layout that encourages selective reading. If it has a significant fault, it is the lack of clinical details to flesh out the plentiful legal cases. It may seem to some like a primer for students of law, but it is in fact intended for, and essential for, practising clinicians.

Every department of child health should have a copy of this book, as well as every CAMHS service.
