Background and Aims Preterm infants will begin the transition from tube to suck feeds at ~34 weeks’ corrected age. Our aim was to compare physiological stability in two positions for bottle feeding preterm infants, the “cradle hold” versus a “side-lying” position.

Methods Randomised crossover trial of infants < 34 weeks’ gestation at birth, ≥ 34 weeks’ corrected gestation at study, receiving ≥ 2 two sucking feeds/day. Feeds were studied on successive days. A pulse oximeter (PO) measured oxygen saturation (SpO2) and heart rate (HR), before, during and for 30 minutes after feeds. Continuous data were compared with paired t-tests, proportions compared with χ2.

Results 25 study infants were, mean (SD) 29(3) weeks gestation and 1158(479)g at birth and mean (SD) 37(2.4) wks corrected age and 2740 (589)g at study.

Abstract 343 Table 1

<table>
<thead>
<tr>
<th></th>
<th>Cradle</th>
<th>Side-lying</th>
<th>p value</th>
</tr>
</thead>
<tbody>
<tr>
<td>SpO2 mean(SD)</td>
<td>94(6)</td>
<td>95(6)</td>
<td>0.55</td>
</tr>
<tr>
<td>HR mean(SD)</td>
<td>163(14)</td>
<td>156(15)</td>
<td>0.09</td>
</tr>
<tr>
<td>SpO2 &lt; 80% (%)</td>
<td>17(68%)</td>
<td>14(56%)</td>
<td>0.39</td>
</tr>
<tr>
<td>HR &lt; 100bpm (%)</td>
<td>5(20%)</td>
<td>10(40%)</td>
<td>0.12</td>
</tr>
<tr>
<td>Proportion of feed consumed mean (SD)</td>
<td>82(25)</td>
<td>87(20)</td>
<td>0.08</td>
</tr>
</tbody>
</table>

Eight study infants were receiving oxygen or respiratory support. In these 8 infants 5/8 (62%) versus 7/8 (87%) in side and cradle feeding positions experienced a SpO2 < 80% (p=0.25) during study feeds.

Conclusions Little difference in physiological stability was seen between the two bottle feeding positions. Both methods may be appropriate for the transition from tube to bottle feeding in preterm infants.

ADIPOCYTOKINE LEVELS IN CORD BLOOD OF PRETERM AND TERM NEWBORN INFANTS

doi:10.1136/archdischild-2012-302724.0344

RC Silveira, AC Terrazan, RS Prociunay. Universidade Federal do Rio Grande do Sul and Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil

Background Few studies have presented data on adiponectin and leptin levels comparing small and appropriate for gestational age, and very low birth weight preterm and term newborns.

Aim To compare levels of adiponectin and leptin in cord blood of full term and very low birth weight preterm infants, and determine its relation with birth weight and being small for gestational age.

Methods Cross sectional study of preterm with gestational age (CA) ≥32 weeks and birth weight ≤1500 grams (VLBW), and term newborns born at tertiary hospital between January 2010 and May 2011. Exclusion criteria were presence of major congenital malformation, metabolism inborn errors, chromosomal anomalies. Adiponectin and leptin cord blood levels were determined by ELISA kits (R&D Systems).

Results Included 127 newborns: 55 VLBW preterm and 72 term newborns. There were no statistical differences regarding maternal gestational diabetes, urinary tract infection, age and BMI. Adiponectin levels were significantly higher in term than in preterm newborns: 2.42±0.22 pg/ml versus 1.57±0.74 pg/ml (p<0.001), respectively; leptin levels were similar in both groups: 1.25±0.90 pg/ml and 1.38±0.99 pg/ml (p=0.481), respectively. Despite being adequate or small for gestational age, VLBW preterm newborns showed lower levels of adiponectin than term newborns (p<0.001), and there were no statistically significant differences for leptin levels. In the linear regression, prematurity was the only independent variable associated to low levels of adiponectin (p<0.001).

Conclusion Prematurity is the main determinant factor for lower adiponectin levels in umbilical cord blood of newborns.

ANALYSIS OF ANTIOXIDATIVE STATUS OF HUMAN MILK AND ITS VARIATIONS AT DAY AND NIGHT TIME

doi:10.1136/archdischild-2012-302724.0345

‘S Baggi, ‘L Pauli, ‘J Reinsberg, ‘B Zur, ‘IP Bartmann, ‘A Mueller. ‘Department of Neonatology, Children's Hospital, University of Bonn; ‘Department of Gynecological Endocrinology, University of Bonn; ‘Department of Clinical Biochemistry, University of Bonn, Germany

Introduction Human milk (HM) contains antioxidant enzymes such as superoxide dismutase (SOD), glutathione peroxidase (GSH-Px) and catalase. Melatonin (MT) shows antioxidative properties both directly by stimulating the activities of antioxidant enzymes and indirectly by scavenging free radicals. The aim of this study was to evaluate the effect of MT status on the level of SOD, GSH-Px and the total antioxidant capacity (TAC) of HM.

Material and Methods 114 samples of HM were collected from 22 healthy women during daytime (DT; 10a.m.-9.59p.m.) and nighttime (NT; 10p.m.-9.59a.m.). MT, SOD, GSH-Px3 levels and TAC were assayed and compared between DT-HM and NT-HM. Moreover, the Pearson’s correlation coefficient was calculated between MT and SOD, GSH-Px3 and TAC.

Results MT showed a circadian rhythm with high levels at NT and low levels at DT (mean±SEM; 9.2±1.2 vs. 2.0±0.3 pg/ml, respectively, p<0.0001), while SOD, GSH-Px3 and TAC had no circadian changes in HM (p>0.05). There was no correlation between MT levels and SOD, GSH-Px3 levels and TAC.

Conclusion The MT status influence neither SOD and GSH-Px3 levels nor TAC of HM. It should be pointed that our results represent only the effect of MT on the extracellular component of the antioxidant system and it does not exclude the possibility that high MT concentrations in HM may induce the intracellular and mitochondrial antioxidant enzyme system in the gastrointestinal tract.

EFFECTS OF BOLUS AND CONTINUOUS ENTERAL FEEDING ON SPLENCHNIC AND CEREBRAL TISSUE OXYGENATION EVALUATED BY NEAR INFRARED SPECTROSCOPY

doi:10.1136/archdischild-2012-302724.0346

L Corvaglia, S Martini, E Legnani, B Battistini, A Aceti, G Faldella. Neonatology and Intensive Care Unit - Sant’Orsola-Malpighi Hospital - University of Bologna, Bologna, Italy

Background and Aims Bolus and continuous tube feeding represent the most frequently used enteral feeding techniques in preterm infants, but the best strategy is not yet established. Near-Infrared Spectroscopy (NIRS) provides a noninvasive monitoring of splanchic...
oxygenation, which may play a role in the multifactorial pathophysiology of necrotizing enterocolitis (NEC).

The aim of this study is to evaluate by NIRS the effects of bolus and continuous enteral feeding on splanchnic and cerebral oxygenation in preterm infants with normal feeding tolerance.

**Methods**

Eighteen healthy preterms (GA 27–32 weeks), tolerating at least 100 ml/kg/day of fortified human milk or preterm formula, underwent a 6-hours simultaneous monitoring of cerebral and splanchnic oxygenation using NIRO-200 oximeter. Sensors were placed on frontal and sub-umbilical region. During the monitoring they randomly received a 10-minutes bolus meal and a 3 hours continuous meal.

Recorded values of cerebral and splanchnic Tissue Oxygenation Index (TOI) were clustered in 5-minutes intervals and compared between different feeding techniques using Wilcoxon Signed Ranks Test. Statistical significance was set at p≤0.05.

**Results**

Splanchnic oxygenation significantly decreased (p<0.05) during continuous feeding, from 1.30±0.36 hour after the beginning to almost the end of the feed. No differences were found on cerebral oxygenation.

**Conclusions**

To the best of our knowledge, this is the first study comparing the effects of different feeding techniques on splanchnic and cerebral oxygenation in preterms. A significant reduction in splanchnic oxygenation was observed during continuous enteral. A possible role of these findings on the multifactorial NEC pathogenesis remains to be investigated.

**Background and Aims**

The main goal of this study was to determine the necessity of folic acid supplementation in preterm infants.

**Methods**

Infants born ≤32 weeks of gestation were included in the study with parental consent. Blood samples for the determination of serum folate levels were obtained on days 14 and 28 postnatally, as well as 36 weeks postconceptionally (or just before discharge if patients are discharged before 36 weeks) – samples A, B and C, respectively. Infants were divided into three groups based on mode of feeding: human breast milk (HBM), fortified HBM or preterm formula (PF).

**Results**

A total of 162 preterm infants were enrolled in the study: 17(10.5%) of whom received HBM alone, 94(58%) received fortified HBM and 51(31.5%) were fed with PF. Comparisons between groups revealed that preterm infants in the fortified HBM and PF groups to have significant higher serum folic acid levels in samples C compared to those receiving HBM alone (p=0.001 for both). None of the preterm infants included developed folate deficiency during the study period.

**Conclusion**

This is the largest and most comprehensive clinical study to date evaluating the need for folate acid supplementation in preterm infants who were fed using either modern PFs or milk fortified with HBM. Our results suggest that fortified HBM use in preterm infants can alleviate the need for further folic acid supplementation. On the other hand, in preterm infants who are unable to receive HBM folic acid support can be provided with PFs.

**Background and Aims**

The amino acid glutamine has been shown to reduce the number of serious neonatal infections in very preterm children (<32 weeks of gestation), which may benefit long-term brain development. The aim of this study was to elucidate potential effects of glutamine supplementation on brain development in very preterm children at school-age.

**Methods**

First, we investigated growth trajectories of head circumference, weight, and length in the first year for 65 very preterm children that originally participated in a randomized controlled trial on enteral glutamine supplementation between day 3 and 30 of life. Second, we measured brain structure volumes and white matter integrity for 52 very preterm children at school-age, using magnetic resonance imaging (MRI) and Diffusion Tensor Imaging (DTI), respectively. Furthermore, differences in functional outcomes were explored. Group differences were tested using ANOVA statistics.

**Results**

Glutamine supplementation was associated with improved growth trajectories of head circumference in the first year of life (d=0.66, p=0.03). Furthermore, glutamine supplementation increased white matter (d=0.54, p=0.03), hippocampus (d=0.47, p=0.02), and brain stem (d=0.54, p=0.04) volumes at school-age. All differences were strongly related with the number of serious neonatal infections (all p<0.02). Glutamine supplementation did not influence measures of motor, cognitive, and behavioral functioning at school-age.

**Conclusions**

We found evidence that reduction of serious infections by neonatal glutamine supplementation improves head growth in the first year of life, as well as brain structure volumes at school-age. This suggests an early programming effect of nutritional intervention with enteral glutamine.

**Background**

Extremely preterm infants often experience growth failure and adequate nutritional supply may be difficult to achieve. It is still debated to what extent nutrition affects growth at an early stage in life. The aim of this study was to explore associations between energy and macronutrient intakes and growth.

**Methods**
