Background and Aims Preterm birth is associated with raised blood pressure (BP) and other features of the metabolic syndrome in later life, but effect sizes and biological mechanisms are unknown. We conducted a meta-analysis to address these associations in adult life.

Methods We performed a systematic review and meta-analysis of studies in which metabolic syndrome associated indices were compared in adults (≥18 years of age) born preterm (<37 weeks gestation) and at term (37–42 weeks gestation). Outcome measures included: systolic blood pressure (SBP), diastolic blood pressure (DBP), BMI, percentage fat mass and fasting plasma levels of lipids, glucose and insulin.

Results Data from 27 studies and 306,123 adults (16,094 preterm, 290,029 term) were included, with an average outcome age of 26.1 years. In adults, preterm compared with full-term birth was associated with significantly higher SBP (mean difference [95% confidence interval]: 4.2 mmHg [2.7, 5.7], p<0.001), DBP (2.7 mmHg [1.2, 4.2], p<0.001) and low density lipoprotein (LDL) (0.14 mmol/L [0.05, 0.22], p=0.01). Meta-regression revealed a significant gender effect, with 3.0 mmHg greater SBP in preterm compared to full-term men (95%CI: 1.3, 4.7, p=0.002); for DBP this difference was 2.1 mmHg greater (0.6, 3.6, p=0.009).

Conclusions Preterm compared to term birth, is associated with higher blood pressure and LDL in adult life. Women born preterm appear to be at greater risk than men born preterm. Follow-up of older subjects born preterm will be required to determine if the effects we observe are exacerbated by age.

354 ADIPOCYTKINES OMENTIN AND VASPIN ARE UPREGULATED IN LARGE FOR GESTATIONAL AGE FETUSES AT TERM

doi:10.1136/archdischild-2012-302724.0354

Background and Aims Fetal macrosomia is associated with significant perinatal and long-term complications, including higher risk for later development of insulin resistance/metabolic syndrome. Besides regulating whole body metabolism, adipocytokines have been implicated in fetal growth. We aimed to investigate circulating concentrations of omentin-1 and vaspin (important adipocytokines, regulating glucose metabolism and insulin sensitivity) in fetal samples from large-for-gestational-age (LGA) and appropriate-for-gestational-age (AGA) pregnancies and correlate them with several maternal and fetal anthropometric/clinical variables.

Methods Sixty five LGA (14 born from mothers presenting with gestational diabetes mellitus and 51 born from non-diabetic mothers) and 35 AGA singleton full-term infants were recruited. Determination of cord blood omentin-1 and vaspin concentrations was performed by enzyme-linked immunosorbent assay.

Results Cord blood omentin-1 concentrations were significantly higher in LGA compared to AGA neonates (b=0.119, p=0.002, SE 0.036), after controlling for confounding factors. Similarly, cord blood vaspin concentrations were significantly elevated in LGA cases, compared to AGA controls (p=0.011). Finally, cord blood omentin-1 concentrations were lower in cases of vaginal delivery (b=-0.072, p=0.020, SE 0.030), after controlling for group.

Conclusions Higher concentrations of omentin-1 and vaspin in LGA compared to AGA fetuses, probably suggest the potential role of both adipocytokines in intrauterine growth, as well as their possible implication in the metabolic disturbances characterizing fetal macrosomia both in the short- and long-term. Vaginal delivery-associated inflammation may account for the lower cord blood omentin-1 concentrations.

355 FETAL GROWTH IS ASSOCIATED WITH ALTERED EXPRESSION OF IMPRINTED GENES IN THE PLACENTA

doi:10.1136/archdischild-2012-302724.0355

Background and Aims Both low and high birthweight is associated with adverse health outcomes throughout life. Altered expression of imprinted genes which regulate fetal and placental growth may be one mechanism linking the environment and later disease risk. We have studied the expression of candidate imprinted genes in placenta with respect to anthropometric parameters at birth.

Methods 58 term placentas (27 male) were obtained from the Edinburgh Reproductive Tissue BioBank. Pregnancies complicated by congenital abnormalities or diabetes were excluded. Gene expression was analysed using real-time PCR.

Results Median birthweight was 3900g (interquartile range: 2949–4540g). Insulin-like growth factor 2 (IGF2) mRNA levels correlated positively with standard deviation scores for birthweight (Spearman’s rho=0.355, p=0.005), head circumference (Spearman’s rho=0.424, p=0.001) and length (Spearman’s rho=0.259, p=0.041). Growth factor receptor-bound protein 10 (GRB10) mRNA levels correlated negatively with birthweight standard deviation score (Spearman’s rho=−0.221, p=0.048). The expression of two other imprinted genes, FHLDA2 and ZIM2 showed no relation to size at birth.

Conclusion Both IGF2 and GRB10 are imprinted in the placenta and impact on fetal and placental growth. IGF2 is paternally imprinted and increased expression is implicated in overgrowth disorders; in contrast, GRB10 is maternally imprinted in trophoblasts and disruption in mice leads to overgrowth. Additionally, GRB10 has recently been identified as having a role in insulin signaling. As genomic imprinting is under epigenetic regulation, these targets are strong candidates for exploration of environmentally influenced non-Mendelian effects on fetal size and developmental programming.

356 ALBUMIN SYNTHESIS RATES IN VLBW INFANTS - EFFECTS OF HIGH DOSE AMINO ACID AND LIPID ADMINISTRATION FROM BIRTH ONWARDS

doi:10.1136/archdischild-2012-302724.0356

Introduction Albumin is one of the most important proteins in plasma and plays a key role in physiological processes like preservation of colloid osmotic pressure and binding of bilirubin and drugs. However, albumin concentrations are often low during the first days of life in preterm infants.

We hypothesized that early parenteral lipid and high dose amino acid (AA) administration from birth onwards to very low birth weight (VLBW) infants increases hepatic albumin synthesis rates and albumin concentration.

Methods Inborn VLBW infants were randomized to one of three different parenteral nutritional regimens within 48 hrs after birth...
At postnatal day 2, infants received a primed continuous infusion of $^{[13C_6,15N]}$leucine. Mass spectrometry was used to determine the fractional and absolute albumin synthesis rates (FSR and ASR, respectively).

**Results** Albumin FSR, concentration, and ASR were not significantly different between groups (Figure 2; median, IQR).

**Conclusion** Albumin concentration was in normal range in all groups. Albumin synthesis rates and concentration are not increased upon introduction of 2g lipids/(kg.d) and 3.6g AA/(kg.d) from birth onwards.

**Abstract 357 Figure 1** Human milk BSSL at different study points

**Conclusions** The increased levels of human milk BSSL could compensate for low endogenous capacity to digest dietary fat in early life as efficient absorption of lipids is important, not only for energy utilization but also for optimal growth and functional neurodevelopment.

**Background and Aims** Human milk (HM) has a number of anti-oxidant constituents which may protect newborns against oxidative damage. Poor HM production is the most frequent cause of breastfeeding failure. Galactagogues are believed to stimulate initiation and maintenance of HM production. Herbal tea containing fenugreek has recently been presented in the market. We aimed to compare global oxidant and antioxidant capacity of HM among mothers drinking galactagogue herbal tea or not.

**Methods** Volunteer mothers 18–35 years of age without any antenatal or perinatal risk factors. Milk samples were collected in the first day after delivery. Mothers were randomly assigned to herbal tea (n=40) and placebo (n=40) groups. In first and second samples TAC, TOS and OSI were similar in both groups.

**Results** Subjects were randomly assigned to herbal tea (n=40) and placebo (n=40) groups. In first and second samples TAC, TOS and OSI were similar in both groups. TAC (p=0.375 and p=0.058) was lower and TOS (p=0.382 and p=0.118) was higher in second samples compared to first samples in both groups but not significantly. In second samples OSI (p=0.024 and p=0.007) increased significantly compared to first day in each group.

**Conclusions** Galactagogue herbal tea used in this study has no effect on global oxidant and antioxidant status of HM. Oxidative stress index increases in course of lactation compared to colostrum.

**Background and Aims** Human milk (HM) contains the major part of BSSL. Data regarding the dynamic changes of human milk BSSL are scarce. The aim of this study was to evaluate the changes of human milk BSSL content at different stages of lactation by proteomic techniques.

**Methods** We designed a prospective longitudinal study. Human milk samples were collected from 18 healthy mothers who delivered a singleton term newborn (gestational age 37–41 weeks) on the 3rd, 7th, 15th, and 60th postpartum day. Proteomic techniques were carried out to evaluate different profile expression of BSSL in milk: in particular SDS-PAGE analysis coupled with LC-MS MS mass spectrometry.

**Results** BSSL levels increased significantly from the 3rd to the 60th postpartum day (figure).
