Background  The segmental spinal cord syndrome is defined clinically as a neurological injury (incomplete or complete) sensory, motor and autonomic.

Results  13 year old female, previously healthy with a sudden onset of severe pain in the inferior limbs, with loss of strength and sensitivity. No history of fever, recent trauma, infection, vaccination or similar episode. The physical examination revealed areflexic flaccid paraplegia, abolished postural sensitivities, painful hypoesthesia with sensitive level at T8, bilateral indifferent cutaneous plantar reflex response and vesical globule.

A brain and spinal cord magnetic resonance imaging (MRI) study showed a discrete hyperintensity on the conus, and cerebrospinal fluid analysis was normal. She was hospitalized admitting a possible diagnosis of transverse myelitis and medicated with methylprednisolone intravenously. Due to the absence of clinical improvement, at day five MRI was repeated showing extensive hyperintensity of the conus with restricted diffusion, which extended to the level of T10, diagnostic hypothesis of acute transverse myelitis or acute ischemic injury was made. An etiological study was conducted presenting heterozygosity for Factor V Leiden. On day 32, after submission to physiotherapy, with slight improvement of proximal weakness in the lower limbs, a new MRI showed spinal cord atrophy.

Conclusions  In this case, the main challenge is to establish the diagnosis and its etiology. Clinically, transverse myelitis is the most probable diagnosis although by imaging, one cannot exclude spinal cord infarction. Regardless of this issue, the overall prognosis, conditioned by severe initial dysfunction and no recovery in the first 24 hours, is unfavorable.

Conclusions  Low level of self-assessment and lack of appearance acceptance may lead to disturbances with physical and mental health.

In Poland dietary supplements and nutrients are sold without prescription even in filling stations and supermarkets and we afraid that young people will abuse them to create their figure according to their imagine.

The proper nutrition is important at every period of human life but particularly in adolescence.

The aim  Estimation of the frequency of regular consumption of particular meals and the characterization of nutritional habits of junior high school pupils.

Methods  The examinations included 986 students from junior high schools (435 boys and 551 girls) at the mean age 13 years and BMI 19.28±2.85 kg/m² (girls) and 19.90±4.51 kg/m² (boys). An anonymous standardized questionnaire concerning nutritional behaviors was used in the study.

Results  Breakfast was eaten regularly by 71.7% (67.6% girls and 76.8% boys); second breakfast: 36.7% (38.1% girls and 34.5% boys); lunch: 87.8 (84.9% girls and 91.0% boys); desert 22.1% (21.7% girls and 22.3% boys); supper: 73.9% (66.5% girls and 82.8% boys). Basic meals were more often omitted by girls than by boys, 33.6% of girls and 29.0% of boys eat something among the main meals. It should be pointed out that 25% of these young people eat their meals alone. Nearly half of the examined group eat chips, cakes, sweets like Snickers, Mars etc. and drink cola, sprite, pepsi. When pupils were asked about the frequency of fast food consumption 2/3 of them answered “sometimes”. The answer “never” was chosen by 19.1% of girls and 18.2% of boys.

Conclusion  The examined group of pupils showed many nutritional mistakes and the way of nutrition becomes far from traditional Polish pattern and becomes similar to nutritional model present in USA and West Europe.

Dynamic physical and psychological changes connected with adolescence are associated with focusing on appearance. The difference between the imagine figure and real appearance can become a source of frustration and dissatisfaction.

The aim  Assessment of body weight acceptance and different actions aiming at appearance improvement among Polish students from junior high schools.

Methods  The examinations included 986 students from junior high schools (551 girls and 435 boys) at the mean age 15 years and BMI 19.28±2.85 (girls) and 19.90±4.51 (boys). An anonymous standardized questionnaire concerning nutritional behaviors was used.

Results  Dissatisfaction with body mass and general appearance was declared by 31.4% boys and 40.6% girls. The majority of these girls used different weight-loss diets (reduction, low-carbohydrate, protein, yoghurt and fruit diets) and nonconventional diets such as Atkins’ and South Beach. Supplements which stimulate fat tissue burn, metabolic process and thermogenesis and such products as Alli, Bio CLA, Linea and Therm Line II were the most popular. The boys declared taking the ergogenic aids (vitamin and mineral preparations) and supplementation with protein or carbohydrate. The reduction of body mass was the goal for 8% of boys and they also decided to start a weight-loss diet.
questionnaire. Different behavior of children has been evaluated: perfectionism, ambition, self-esteem, control of food portions eaten, stress-eating as well as paying attention to other’s opinion and appearance.

**Results** Daughters of younger fathers significantly more often ate in response to worries or problems (p=0.017) and had poorer self-esteem compared to the daughters of older fathers (p=0.0013). The sons of fathers with higher education significantly more often pointed out slim figure as important (p=0.0089). Daughters of fathers with primary education often had low self-esteem compared to their friends (p=0.014).

**Conclusions**

1. The independent predictors of eating disorders father’s age and education have been an important modifying factor. Children (especially daughters) of the young, uneducated fathers have more often shown abnormal behaviour and habits in nutrition, indicating anorexia.

2. Mother’s age and education have not affected the eating disorders of their children.

**ASSOCIATION BETWEEN OBESITY AND DEPRESSION IN EMIRATI ADOLESCENTS**

**Background** Overweight, obesity is rapidly increasing among children in United Arab Emirates (UAE). This study aimed to determine the prevalence of depression and its relation with obesity in adolescents.

**Methods** The study sample included 1018 adolescents (12–18 years) from a random sample of 8 schools out of 114 schools in Al Ain district of Abu Dhabi Emirate in UAE. We estimated self-reported symptoms of depression using the Arabic Beck’s Depression Inventory (BDI). BMI ≥85th and ≥95th percentiles were used to define overweight and obesity according to the 2000 CDC growth charts.

**Results** The prevalence of depression according to the BDI (cut-offpoint:19) was 10.7%. Girls were more likely (OR=3.97, 95%CI: 1.11–14.23) to have depression (12.2%) compared to boys (7.0%). A high proportion of adolescents (83.6%) were overweight and obese. There was a significant (p=0.047) correlation between overweight and obesity and depression after adjustment for gender, age, ethnicity, and income level.

**Conclusion** There is disparity in prevalence of depression by gender. There is significant correlation between overweight, obesity and depression irrespective of age, gender, ethnicity and income.

**RADIOLOGICAL ASSESSMENT OF CAPITAL REALIGNMENT SURGERY FOLLOWING SLIPPED CAPITAL FEMORAL EPhipHYSIS (SCFE)**

**Introduction** The pinning in situ of slipped capital femoral epiphysis (SCFE) is the accepted gold standard treatment. However, the resultant deformity from pinning of severe SCFE creates an altered femoral head-neck relationship. This contributing to femoroacetabular impingement and eventually the development of osteoarthritis.¹

The principal investigator has previously published on the use of two radiographic indices, alpha angle and displacement from Kleins line, surrogates of impingement, to evaluate the femoral head neck relationship in mild to moderate grade severity SCFE’s. treated by pinning in situ.²

Subcapital realignment surgery through surgical hip dislocation has been performed in moderate to severe SCFE in an attempt to restore femoral head-neck geometry.³ We describe the use of the two previously recognised radiographic parameters in the setting of capital realignment for the treatment of severe SCFE.

**Aims** To assess the radiological outcomes; alpha angle, and displacement from Kleins line in patients having undergone capital realignment, compared with normative data.

**Methods** We retrospectively reviewed 11 patients (6 males, 5 females mean age 12.2 years with moderate to severe (1 moderate: 10 severe) SCFE having undergone capital realignment between 2009 and 2011.

**Results** Alpha angles restored to normal range in all patients. Kleins line offset was restored to positive displacement in 7 patients, with 3 patients noted to demonstrate a new radiographic finding termed pistol grip type deformity.

**Discussion** The radiographic parameters of alpha angle and Kleins line offset are useful in quantifying the restoration of proximal femoral anatomy following capital realignment.

**ISOLATED TORSION OF INFUNDIBULUM OF THE RIGHT FALLOPIAN TUBE IN A 12-YEAR-OLD GIRL**

**Background** Prepubertal gynecomastia is an extremely rare condition usually requiring surgical treatment, especially in case of class III gynecomastia. This study presents cases treated with a new surgical treatment.

**Methods** Five patients were treated at the Authors’ Unit for class III gynecomastia between January 2010 and December 2011 using a modified technique of periareolar incision. Aesthetic results and possible complications of this technique were then observed.

**Results** All patients were properly treated without the need of further surgery for skin resection. One patient developed stroma, treated with suction; one patient showed hematoma, treated with hot packs for 3 weeks. All patients and their parents were satisfied with the aesthetic results obtained. All patients resumed sport activities 4 weeks after surgery. It was not possible to observe intraoperative complications.

**Conclusion** The technique used meets safety and efficacy standards for the treatment of this type of pediatric gynecomastia. It also offers the best possible aesthetic results with minimum complications which can be treated without the need of further surgery.
