Results proforma. Cystic fibrosis. Results of plasma vitamin A, D (Total 25 OH Vit D)

Method

NHS Trust.

Background
determine the nomenclature for EDD. The most well characterized in the clinical presentations of EDD is determined by the site and anywhere from the esophagus to the rectum. The heterogeneity in the clinical presentations of EDD is determined by the site and depth of eosinophilic infiltration. The sites of inflammation determine the nomenclature for EDD. The most well characterized of these, eosinophilic esophagitis (EE), eosinophilic gastroenteritis (EG), and eosinophilic colitis or enterocolitis. While the depth of eosinophilic infiltration through the three main layers (mucosa, musculosa and serosa) determines the prominent clinical manifestation. The recent advances in gastrointestinal endoscopy and the increasing awareness and diagnosis of EDD, in my viewpoint, can be of help to add to our understanding of the heterogeneous clinical syndrome under the broad title bronchial asthma.

Here I present a multidisciplinary comparative analysis to prove that EDD and the allergic bronchial asthma can be regarded as two clinical expressions of one disease in two systems that are functionally different but anatomically and embryologically related.

Prevalence of fat-soluble vitamin deficiencies in children with cystic fibrosis

AK Gupta, V Ng, J Garise. Paediatrics, Calderdale and Huddersfield NHS Trust, Halifax, UK

Background

Malabsorption of fat-soluble vitamins is likely in most patients with cystic fibrosis, particularly those who are pancreatic insufficient. Low vitamin levels are associated with poorer clinical status, and reduced lung function. Since the introduction of improved pancreatic enzymes, normal to high fat diets and routine vitamin supplementation, clinical evidence of fat-soluble vitamin deficiency is rarely seen.

Aim

To determine the prevalence of fat-soluble vitamin deficiencies in children with cystic fibrosis in Calderdale and Huddersfield NHS Trust.

Method

Retrospective analysis of vitamin levels performed in children with cystic fibrosis in Calderdale and Huddersfield Trust over a period of six years. Data was available for 19 out of 22 children with cystic fibrosis. Results of plasma vitamin A, D (Total 25 OH Vit D) and E levels for these children were collected on a pre-designed proforma.

Results

Vitamin A, D and E levels were checked for a total of 75, 75 and 76 times respectively over a period of six years. Vitamin E levels were normal. Vit A levels were subnormal on two occasions. However, Vitamin D levels were sub-optimal (< 60nmol/l) on forty occasions and amongst them levels were below 20 nmol/l on three occasions.

Conclusion

Sub-optimal Vitamin D levels are still very common in children with cystic fibrosis despite routine vitamin supplementation.

Spreading of nourishment disorders in schoolchildren population

M Yakoot. Internal Medicine and Pediatrics, Green Clinic and Research Centre, Alexandria, Egypt

OF ONE DISEASE IN TWO DIFFERENT SYSTEMS

SPREAD OF ONE DISEASE IN TWO DIFFERENT SYSTEMS

bronchial asthma, two diseases or an expression of one disease in two different systems

Abstracts
Conclusions The results suggest that in obese children undergoing nutritional interventions longitudinal changes in liver fat content may be associated with change in serum transaminases suggesting novelty in monitoring NAFLD in childhood obesity.

**711 COMPARISON BETWEEN OVERWEIGHT/OBESE (OW/OB) PATIENTS: COELIAC VS NON COELIAC ONES**

doi:10.1136/archdischild-2012-302724.0711

R Mercurio, D Guttadore, M Podiagrosi, A Grimaldi, M Barbato, AM Caiazzo, L Petrarca, A Vania. Dept of Paediatrics and Paediatric Neuro-Psychiatry, 'Sapienza' University of Rome, Rome, Italy

Background and Aims In literature there are case reports of coeliac disease (CD) diagnosed in OW/OB children and studies assessing the body weight excess (EBW) at CD diagnosis. Besides, an incorrect gluten-free-diet (GFD) often leads to EBW. Aim of this study is to assess the effect of a balanced diet in coeliac patients (CP) with EBW compared to matched non-coeliac patients (NCP) with EBW.

Methods and results: In 2006-2010, we selected 8 (4M, 4F, age=11.35±3.79) out of 29 CP we follow; all had EBW (z-BMI=1.98±0.69) and were compliant to the GFD. Follow-up lasted 11.62±1.68 months, with a z-BMI reduction in all cases (z-BMI=1.45±0.10). Among the matched 8 NCP (4M, 4F, age=10.52±3.60), start-up’s z-BMI=2.07±0.59, followed-up for the same period of time, 7 reduced their z-BMI (1.57±0.67), while in 1 it worsened.

Conclusions Despite the limited number of patients, our study underlines the importance of a strict supervision in CP with EBW to improve their nutritional status. We also noticed that the coadherence to a balanced GFD and the consequent effect on z-BMI are better than those among NCP, probably because in CP the nutritional prescriptions are perceived as indispensable for the therapy of CD.

**712 SAFETY AND EFFICACY OF OMEGAVEN IN PRETERM NEONATES WITH PARENTERAL NUTRITION ASSOCIATED LIVER DISEASE**

doi:10.1136/archdischild-2012-302724.0712

1O Genovese, 2A Chiaretti, 1A Mancino, 1A Gatto. 1Paediatric Intensive Care Unit; 2Pedicriatics, Policlinico Gemelli University Hospital, Roma, Italy

Background: Omegaven, a fish oil derived parenteral lipid emulsion rich in omega-3 fatty acids, has been used in the United States under Investigational New Drug applications to treat parenteral nutrition associated liver disease (PNALD) in neonates.

Aims To evaluate the safety profile and changes in serum direct bilirubin levels in preterm neonates with moderate to severe PNALD treated with Omegaven.

Methods: A prospective observational study of parenteral nutrition (PN) dependant neonates with consecutive serum direct bilirubin levels above 3 mg/dL, separated by a minimum of 7 days, who were expected to require PN for at least 3 more weeks were considered for Omegaven therapy. Eligible neonates were treated with Omegaven, as the only lipid infusion, at a maximum rate of 1 g/kg/day. Omegaven therapy was stopped once the serum direct bilirubin level was less than 1 mg/dL on consecutive weeks, or the patient tolerated adequate enteral nutrition to stop PN. The change in serum direct bilirubin was compared using the Wilcoxon signed-rank test.

Results: 17 neonates were eligible for the analysis with a mean gestational age at birth of 26.6 weeks and mean birth weight of 911 g. Omegaven was administered for a median of 57 days. The neonates tolerated Omegaven well, without significant changes noted in the safety indicators (coagulation profile, platelet count, serum triglyceride, glucose, albumine).

Serum direct bilirubin levels decreased significantly during the treatment course (p = 0.05).

Conclusions: Significant decrease in serum direct bilirubin levels was observed in neonates with PNALD; Omegaven was well tolerated.

**713 COMPARISON BETWEEN PROPOFOL VERSUS PROPOFOL-KETAMINE COMBINATION IN PAEDIATRIC UPPER GASTRO-INTESTINAL ENDOSCOPY**

doi:10.1136/archdischild-2012-302724.0713

O Genovese, A Chiaretti, A Mancino, A Gatto. 1Paediatric Intensive Care Unit; 2Pedics, Policlinico Gemelli University Hospital, Roma, Italy

Objective: To assess the safety and effectiveness of the ketamine plus propofol combination versus propofol alone for procedural sedation in pediatric patients undergoing upper GI endoscopy.

Patients and design: A retrospective case series of patients undergoing procedural sedation for upper GI endoscopy was studied. Median age was 6.3 (0.4–13.1) years. 29 patients received propofol alone while 37 patients received propofol plus ketamine; the child’s degree of sedation was scored using the modified Ramsay sedation scale. Procedural success (length of the procedure), adverse effects, recovery time, and vital signs were also measured.

Results: No patient in either group experienced major adverse events or required tracheal intubation. In group receiving ketamine and propofol, the total dose of propofol required was significantly lower than in Propofol alone (3.4±3.2 mg/kg vs. 5.2±3.4 mg/kg; P<0.001). The incidence of hypotension was also significantly lower (10% vs. 37%; P<0.001). Both best analgesia and shorter recovery time were obtained with the propofol-ketamine association. No differences were observed in the degree of sedation and in the awakening quality score between the two groups.

Conclusions: The combination of propofol and ketamine provides a good solution for procedural sedation in during GI endoscopic procedures. Compared to propofol alone, ketamine and propofol results in less hypotension and reduces the incidence of respiratory depression.

**714 RELATIONSHIP BETWEEN ESOPHAGEAL SWALLOW PATTERNS AND REFLUX CHARACTERISTICS IN NEWBORNS WITH SYMPTOMS OF GASTROESOPHAGEAL REFLUX DISEASE**

doi:10.1136/archdischild-2012-302724.0714

F Cresi, SA Liguori, E Locatelli, E Maggione, F Savino, E Bertino. 1Neonatal Intensive Care Unit, Department of Paediatrics; 2Dep of Pediatrics, University of Torino, Torino, Italy

Background and Aims: Transient lower esophageal sphincter relaxations are primarily responsible for GER in healthy infants and plays an important role in preterm and term infants with GER disease (GERD). Gastroesophageal dismotility due to immaturity could also promote impaired swallowing patterns influencing the esophageal clearance. The aim of this study was to investigate the relationship between esophageal swallow patterns and reflux characteristics in newborns with GERD symptoms.
