Methods  Esophageal swallow patterns and refluxes were visually evaluated in preterm and at term bottle fed newborns who underwent Multichannel Intraluminal Impedance (MII) analysis for clinical suspect of GERD. The swallow frequency, the mean Bolus Head Advance Time (BHAT), the mean Total Bolus Transit Time (TBTT) and reflux characteristics (frequency, duration and impedance bolus exposure index) were assessed for each patient.

Conclusions  MII is a valid technique to evaluate esophageal bolus transit and refluxes. Our data support that esophageal motor dysfunction due to immaturity affect esophageal swallowing patterns and esophageal clearance time in GERD newborns.

Abstract 715  DENTAL EROSION AND GASTROESOPHAGEAL REFLUX DISEASE (GERD) IN CHILDREN
doi:10.1136/archdischild-2012-302724.0715

Background  Dental erosion is a complication of gastroesophageal reflux Disease (GERD) in adults; in children, it is not clear if GERD has a role in dental pathologic conditions. Dietary intake, oral hygiene, high bacterial capacity, and decreased salivary flow might contribute individually to GERD development or dental erosion, but their potential involvement in dental erosion from GERD is not agreed. We investigated the prevalence of dental erosion among children with and without GERD symptoms, and whether salivary flow rate to location-specific dental erosion.

Methods  We performed a cross-sectional study of 40 children (ages, 3–6 y) with symptoms of GERD and 30 asymptomatic children (controls); all completed a questionnaire on dietary exposure. Teeth were examined for erosion into dentin, erosion locations, and affected surfaces. All subjects responded a detailed frequency questionnaire related to acidic drinks, foods, and sugar consumption and participated in a clinical dental examination. The caries experience of the children was recorded according to World Health Organization criteria, and erosion was scored according to the Eccles and Jenkins grading scale.

Results  This Survey showed that the prevalence of erosion on palatal surfaces of the primary teeth was 42% in 3–6-year-olds with GERD. This finding to be significantly higher than for healthy subjects (P < 0.05). The salivary flow rate, and frequency of acidic drinks, foods, and sugar consumption were found to be similar in both groups.

Conclusion  This current investigation has showed that GERD children were at an increased threat of developing erosion and caries compared with healthy subjects.

Abstract 716  DOES BLOODY ASPIRATE REFLECT THE STATE OF UPPER GASTROINTESTINAL MUCOSA IN A CRITICALLY ILL NEWBORN?
doi:10.1136/archdischild-2012-302724.0716
R Tomerak, AA El Badawy, AE Eskander, AH Mahmoud. Cairo University, Cairo, Egypt

Background and study aims  Critically ill newborns have many risk factors to develop stress related mucosal lesions (SRML). We used upper endoscopy to evaluate the presence of SRML in these neonates, to know the specificity and sensitivity of the bloody gastric aspirate to detect SRML and to identify the risk factors associated with the presence of SRML and bloody gastric aspirate.

Patients and methods  This is a cross-sectional study done on 100 critically ill newborn after becoming clinically stable. SRML were diagnosed if there is hyperemia, erosions or ulcers in the esophagus, stomach, and/or the duodenum. The association between the various clinico-laboratory findings and the presence of SRML and bloody gastric aspirate were studied.

Results  SRML were found in 77% of neonates in the NICU though frank bloody aspirate was detected in only 22% of neonates. The presence of bloody aspirate showed low sensitivity (24.68%) for the presence of SRML and high specificity (86.96%). The presence of bloody gastric aspirate showed a double fold risk for the presence SRML (OR=2.184, CI=0.584–8.171). Factors associated with SRML...
Background Helicobacter pylori infection is a common infection that affects the human being. This infection also affects the children. Different diagnostic methods such as serology, stool antigen detection, rapid urease test and histology detect this microorganism. The aim of this study was to determined correlation between serology and histology/rapid urease test.

Methods Two groups were selected and matched for age and sex. Seventy seven children with confirmed H. pylori infection as they had positive rapid urease test and histology concomitantly were compared with 77 healthy children. Both case and control groups checked serologically for detection of anti H. pylori IgM, IgG and IgA antibody titers.

Results Three Cut-off points were 3.3 U/ML for IgA, 6.4 U/ML for IgM, and 9.9 U/ML for IgG. Antibody titers were compared with gold standard methods including histologic and rapid urease tests. IgA level had a sensitivity of 64%, specificity of 58%, accuracy of 59.3%, positive predictive value of 31.5%, and negative predictive value of 76.9%. IgM level had a sensitivity of 76%, specificity of 58%, accuracy of 71.3%, positive predictive value of 31.5%, and negative predictive value of 79.3%.

Conclusion These antibodies have a relatively high negative predictive value and a low positive predictive value. So, their negative results are more valuable. The most sensitive antibody is IgM and most specific antibody is IgG.
