Conclusions This study has observed a difference in survival related to oxygen tension status, with a trend to worsening survival from hypoxia through to hyperoxia. Confirmation of this preliminary finding is required in a larger cohort before embarking on a randomised controlled trial.

807 HYPOCORTISOLEMIA IN SICK CHILDREN ON PAEDIATRIC INTENSIVE CARE UNIT (PICU): TRANSIENT OR CAUSE FOR CONCERN

doi:10.1136/archdischild-2012-302724.0807

Background and Aims Cortisol insufficiency has been reported in sick children with severe sepsis, post-cardiac surgery, and may contribute to rapid cardiovascular collapse. Hypothalamic-pituitary-adrenal axis dysfunction may play a role in low-cardiac-output syndrome. We performed a review of PICU patients to describe cortisol levels in those with suspected adrenal insufficiency.

Methods Retrospective review of PICU patients (general and cardiac cases) over 6 months from April to September 2011, who had cortisol levels checked and/or received hydrocortisone.

Results Total PICU admissions were 519, of which 30 (5.7%) patients had cortisol levels. Most common indication for cortisol assessment was refractory hypotension (73%) in cardiac and septic patients. 12/30 (40%) had cortisol levels < 500nmol/L (suboptimal response to stress), and 2/12 had undetectable cortisol levels. Of 12 with low cortisol, 50% were post-operative cardiac neonates and 50% were mix of other post-operative and chronic illness, 75% were hypotensive on inotropes and one-third of these received hydrocortisone in PICU. Hydrocortisone dose used was variable. None of the septic children had low cortisol in our study group. 50% of hypocortisolemia patients were followed up by endocrine team and had normal cortisol levels on follow-up. 10/30 (33%) patients with suspected adrenal insufficiency died (50% had hypocortisolemia).

Conclusions Our data shows that hypocortisolemia can be transient in sick PICU patients, and may play a role in low-cardiac-output syndrome. There is a need to identify these complex patients with high mortality, and have a uniform management policy jointly with advice and follow-up by the Endocrine team.

808 UNPLANNED READMISSION TO THE PAEDIATRIC INTENSIVE CARE UNIT (PICU), CAN IT BE PREVENTED?

doi:10.1136/archdischild-2012-302724.0808

D White, H Cosrato Bachmayr. Paediatric Intensive Care Unit, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK

Background and Aims It is known that patients readmitted to the PICU during the same hospitalization have significantly adverse outcomes. Prevention of unplanned readmissions to the Paediatric Intensive Care Unit (PICU) is a key factor when considering the quality of care received by our patients.

Methods All admissions to the PICU during 2011 were examined and all readmissions to the unit were identified. A readmission was defined as those requiring PICU < 48 hours following discharge. Patients who were readmitted for an elective procedure within the specified time were discounted.

Results During 2011, 511 children had 615 admissions to the PICU. 12 children were readmitted for acute care having deteriorated in the ward setting. 2 of the 12 children required 2 readmissions. 5 of the readmissions took place between April and September. The remaining 9 occurred during October to March.

Conclusions It remains a subject of debate as to whether or not any of the readmissions could have been avoided as hindsight is always easy. With nearly double the amount readmissions occurring during the winter months, it could be argued that the children were discharged prematurely due to bed pressures. This a serious concern and one which we will continue to monitor.
