Background and Aim Although hypoalbuminemia has been recognized as a marker of poor outcome in adult patients, this association has not been demonstrated in a general population of pediatric critically ill children, and studies have not considered non-nutritional factors that may influence albumin concentrations. This study aimed to determine whether hypoalbuminemia is associated with mortality and morbidity of critically ill children while considering the clinical severity of the patients.

Methods We conducted a before-after study of previously healthy children with fever, aged 1 month to 16 years, who attended the pediatric ED of the Erasmus MC - Sophia, Rotterdam, The Netherlands. The outcome variables studied were ICU mortality, severity of organ dysfunction, free-ventilator days and free-ICU days. The outcome variables were as follows: nutritional status, Pediatric Index of Mortality (PIM 2), serum albumin, C Reactive Protein and lactate concentrations. Children with liver failure and chronic kidney disease were excluded.

Results Mean serum albumin concentration upon admission among survivors was 3.16±0.66 versus 2.65±0.67 in non-survivors (p=0.015). The mortality rate was 6.4% (11/178). In a multiple logistic regression model, adjusting for PIM 2 score, lower albumin concentrations were independently associated with increased organ dysfunction (OR: 0.18, 95% CI: 0.06–0.53; p=0.002) and mortality (OR: 0.22, 95% CI: 0.07–0.76; p=0.017). In a multiple linear regression model, adjusted for PIM2, malnutrition and other potential confounders, lower albumin concentrations were associated with fewer free-ventilator days (p=0.024) and free-ICU days (p=0.028).

Conclusions Children with hypoalbuminemia at admission are at a greater risk of organ dysfunction and mortality, and longer time of mechanical ventilation and length of ICU stay, independent of clinical severity and nutritional status.

**826 BEDSIDE C-REACTIVE PROTEIN TESTING IN FEBRILE CHILDREN REDUCES LENGTH OF STAY AT THE EMERGENCY DEPARTMENT**

doi:10.1136/archdischild-2012-302724.0826

**827 EVOLUTION OF OTITIS MEDIA IN CHILDREN OF THE FIRST 7 YEARS OF LIFE IN MOLDOVA**

**Abstracts**

**Background and Aim** C-Reactive Protein (CRP) is an important diagnostic marker in the evaluation of febrile children. Aim is to study if bedside CRP testing reduces the length of stay (LOS) of febrile children at the emergency department (ED).

**Methods** We conducted a before-after study of previously healthy children with fever, aged 1 month to 16 years, who attended the pediatric ED of the Erasmus MC - Sophia, Rotterdam, The Netherlands, between 2008–2011. Bedside CRP testing was implemented in 2009, while conventional CRP testing remained optional. We used multivariable linear regression analysis to study the effect of introducing bedside CRP testing on (log transformed) LOS at the ED.

**Results** In the pre-implementation cohort we included 651 children, 519 (49%) had a conventional CRP ordered at the discretion of the physician. In the post-implementation cohort we included 1576 children; 703 (51%) had bedside CRP and 223 (16%) conventional CRP testing. Bedside CRP reduced the median LOS to 148 minutes (interquartile range (IQR): 109–201); in the pre-implementation cohort this was 176 minutes (IQR: 132–231) (p<0.001). LOS of children with conventional CRP was similar between the two cohorts. Other important determinants of (log)LOS were hospitalisation (beta: 0.32 (se: 0.04), p<0.001), transfer to a different hospital (0.55 (0.04), p<0.001) and shift of presentation (daytime: 0.25 (0.05), p<0.001; evening: 0.19 (0.03), p<0.001; night = reference).

**Conclusion** CRP bedside testing substantially reduces LOS at the ED for children with fever. Other important determinants of LOS were hospitalisation and time of presentation.

**828 VITAMIN D STATUS IS NOT ASSOCIATED WITH THE RECURRENT WHEEZY IN INFANCY**

**Abstracts**

**Background** Otitis media (OM) is a common problem for primary care, pediatricians and otorhinolaryngologists.

**The Aim** of our work is to analyze the evolution of OM in children of the first 7 years of life after respiratory tract (RT) pathology.

**Subjects** Children from 1 to 7 years of life (2785) without evident OM after standard treatment of RT pathology - bronchitis, pneumonia; RT infection-prone children, chronic nasal breathing difficulties. Healthy children of the same age were included in the control group.

**Outcome measures** Screening tympanometry, otoscopy; audiometry assessment and otomicroscopy for children who failed the screening tests, parapharyngeal sinuses evaluation, otological follow up for children with middle ear pathology during 2 years.

**Results** We diagnosed OM in 68% of cases from RT pathology group and in 6% of cases from control group (p less than 0.001). Acute middle ear effusion was presented in 53%, chronic OM with effusion in 38%, recurrent OM in 9%. Chronic and recurrent OM was related with RT infection-prone children (p less than 0.01), age younger than 5 years of life (p less than 0.01) and sinusitis (p less than 0.01). Adhesive and chronic OM was recorded during otomicroscopy and surgery in 12% of cases.

**Conclusions** Screening for OM is important for children with recurrent and chronic RT pathology. These groups of patients need comprehensive diagnostic management and intensive treatment, including surgical one. In healthy children OM is a relative rare and temporary condition.
