Background and Aim Although hypoalbuminemia has been recognized as a marker of poor outcome in adult patients, this association has not been demonstrated in a general population of pediatric critically ill children, and studies have not considered non-nutritional factors that may influence albumin concentrations. This study aimed to determine whether hypoalbuminemia is associated with mortality and morbidity of critically ill children while considering the clinical severity of the patients.

Methods We conducted a before-after study involving 178 children admitted to the ICU. The outcome variables studied were ICU mortality, severity of organ dysfunction, free-ventilator days and free-ICU days. The outcome variables were as follows: nutritional status, Pediatric Index of Mortality (PIM 2), serum albumin, C Reactive Protein and lactate concentrations. Children with liver failure and chronic kidney disease were excluded.

Results Mean serum albumin concentration upon admission among survivors was 3.16±0.66 versus 2.65±0.67 in non-survivors (p=0.015). The mortality rate was 6.4% (11/178). In a multiple logistic regression model, adjusting for PIM 2 score, lower albumin concentrations were independently associated with increased organ dysfunction (OR: 0.18, 95% CI: 0.06–0.53; p=0.002) and mortality (OR: 0.22, 95% CI: 0.07–0.76; p=0.017). In a multiple linear regression model, adjusted for PIM 2, malnutrition and other potential confounders, lower albumin concentrations were associated with fewer free-ventilator days (p=0.024) and free-ICU days (p=0.028).

Conclusions Children with hypoalbuminemia at admission are at a greater risk of organ dysfunction and mortality, and longer time of mechanical ventilation and length of ICU stay, independent of clinical severity and nutritional status.

Bedside C-Reactive Protein Testing in Febrile Children Reduces Length of Stay at the Emergency Department

A238

Background and Aims C-Reactive Protein (CRP) is an important diagnostic marker in the evaluation of febrile children. Aim is to study if bedside CRP testing reduces the length of stay (LOS) of febrile children at the emergency department (ED).

Methods We conducted a before-after study of previously healthy children with fever, aged 1 month to 16 years, who attended the pediatric ED of the Erasmus MC - Sophia, Rotterdam, The Netherlands, between 2008–2011. Bedside CRP testing was implemented in 2009, while conventional CRP testing remained optional. We used multivariable linear regression analysis to study the effect of introducing bedside CRP testing on (log transformed) LOS at the ED.

Results In the pre-implementation cohort we included 651 children, 519 (49%) had a conventional CRP ordered at the discretion of the physician. In the post-implementation cohort we included 1576 children, 703 (51%) had bedside CRP and 223 (16%) conventional CRP testing. Bedside CRP reduced the median LOS to 148 minutes (interquartile range (IQR): 109–201); in the pre-implementation cohort this was 176 minutes (IQR: 132–231) (p<0.001). LOS of children with conventional CRP was similar between the two cohorts. Other important determinants of (log)LOS were hospitalisation (beta: 0.32 (se: 0.04), p<0.001), transfer to a different hospital (0.55 (0.04), p<0.001) and shift of presentation (daytime: 0.25 (0.05), p<0.001; evening: 0.19 (0.03), p<0.001); night = reference.

Conclusion CRP bedside testing substantially reduces LOS at the ED for children with fever. Other important determinants of LOS were hospitalisation and time of presentation.
There was no significant correlation between the number of wheezing attacks (p>0.05).

No correlation between vitamin D levels and acute bronchiolitis was found but this may be the result of few numbers of patients that we studied with.

**EVALUATION OF IL-6 AND HIGHLY SENSITIVE CRP VALUE IN CSF AND SERUM CHILDREN REFERRED TO PEDIATRIC EMERGENCY ROOM**

doi:10.1136/archdischild-2012-302724.0829

1A Hamedi, 1H Ayatollahi, 1Pediatrics, 2Mashhad University of Medical Sciences, Mashhad, Iran

**Introduction** Acute bacterial meningitis which is a pediatric emergency with high mortality and morbidity, must be diagnosed and treated promptly. Determination of some inflammatory mediators such as IL-6 and hsCRP were useful in differential diagnosis of bacterial and viral meningitis.

**Objectives** Determination of hs CRP and IL6 in serum and CSF in children suspected meningitis.

**Materials and Methods** From children that hospitalized in pediatric emergency ward and for those performed lumbar puncture, l/cc serum and csf of they were taken to library ward and have measured IL-6 with Elisa method and hsCRP with Immunoturbidimetry method patients were followed up and finally we compared levels of this two mediators.

**Results** From 81 cases, 27 cases (33.3%) were bacterial meningitis 27 cases (33.3%) were viral meningitis and 27 cases (33.3%) were Normal. IL-6 concentration in the csf and serum were significantly raised in cases of bacterial meningitis (P=0.001, P=0/01) but hsCRP concentration in the CSF and serum were not significantly raised in cases of bacterial meningitis (p=0.46, p=0.29). Mean IL-6 in serum in bacterial meningitis was (50.01) and in viral meningitis was (10.64) mean IL-6 concentration in the CSF in bacterial meningitis was (180.74) and in viral meningitis was (39.08) mean hsCRP in CSF in bacterial meningitis was (2.22) and viral meningitis was (1.29).

**Conclusion** The measurement of IL-6 in the CSF and serum is potentially a very useful diagnostic tool for differential diagnosis of bacterial and viral meningitis.

**THE VALUE OF MEAN PLATELET VOLUME IN THE DETERMINATION OF COMMUNITY ACQUIRED PNEUMONIA IN CHILDREN**

doi:10.1136/archdischild-2012-302724.0830

1E Karadag Oncel, 1Y Ozsurekci, 1A Kara, 1S Karahan, 1AB Cengiz, 1M Ceyhan. 1Pediatric Infectious Disease, Hacettepe University Ihsan Dogramaci Childrens’ Hospital; 2Biostatistics, Hacettepe University Faculty of Medicine, Ankara, Turkey

**Background** The aim of this study was to evaluate whether mean platelet volume (MPV) could be used for the diagnostic tool of community acquired pneumonia (CAP) and for making the decision for hospitalization.

**Methods** The computerized records of children aged 1 to 18 years who were diagnosed with CAP based on WHO criteria were evaluated. A standard protocol was followed, and patients with severe CAP were hospitalized. CAP patients were divided into two groups based on disease severity. The control group consisted of age- and gender-matched healthy children who attended the “Well-child” clinic during the study period. Values for hemoglobin, white blood cell count (WBC), platelet count, MPV and C-reactive protein (CRP) obtained on first presentation were recorded for each patient.

**Results** A total of 139 patients were diagnosed with CAP during the study period, 82 (58.9%) of which had severe disease, which required hospitalization, while the remaining 57 (41.4%) were followed-up as outpatients. The control group consisted of 61 healthy children. Patients with CAP had lower MPV values than their healthy counterparts (7.14±0.70 vs. 8.55±1.26 fL, p<0.001). Following ROC analysis, the cut-off value established for MPV was 8.05, which had a sensitivity of 91% and a specificity of 51% for making a diagnosis of CAP. Patients with severe CAP that required hospitalization had significantly higher CRP levels than those who were followed-up on an outpatient basis (p<0.001).

**Conclusions** Our findings suggest that MPV could be used for the diagnosis of CAP in children.

**AN ANALYSIS OF THE PROGRESSIVE CLINICAL DETERIORATION IN THE CASES WITH SUBACUTE SCLEROSING PANENCEPHALITIS**

doi:10.1136/archdischild-2012-302724.0831

S Saygili, C Yarar, G Arslan, E AksuyeK. Pediatrics, Turkish Ministry of Health, Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey

Subacute sclerosing panencephalitis (SSPE) is devastating progressive neurodegenerative disorder of the central nervous system by an aberrant measles virus. SSPE is still important health problem in countries where measles immunization is incomplete and in world regions where genetic polymorphism to this particular infection is present. We aimed to make a retrospective analysis of the clinical and laboratory findings and prognostic factors of children with SSPE.

**Method** A total 55 consecutive cases (22 female, 33 male), aged 5–19 years, followed-up for SSPE at the Pediatric Neurology Department were included. The risk factors for progression time of SSPE from stage I–II to IV according to the criteria of Jabbour examined were gender, age at diagnosis of SSPE, presence of neuroimaging abnormalities, age of patient during measles infection and the antibody index for measles. SSPE risk factors were obtained through a questionnaire via personal interviews and the medical records and were assessed using Mann-Whitney U, Student t and Pearson correlation tests.

**Results** Presence of neuroimaging abnormalities, gender, age at diagnosis of SSPE, presence of neuroimaging abnormalities, age of patient during measles infection and the antibody index for measles were not associated with a progressive clinical deterioration (p>0.05). 66.7 percent of cases were vaccinated with measles vaccine, 43.5 percent of cases have had measles infection before age of 9 months.

**Conclusion** Viral, host and environmental factors are probably involved in the development and progression of SSPE. Successful measles vaccination programmes which accordance with the requirements of that country can protect the population against SSPE.

**ACUTE TRANSVERSE MYELITIS IN A PEDIATRIC CASE OF LYME DISEASE**

doi:10.1136/archdischild-2012-302724.0832

1I Erol, 1B Kilicaslan, 1S Demir, 1H Gulcan, 1F Alehan. 1Department of Pediatrics, Division of Child Neurology; 2Department of Pediatrics; 3Department of Radiology; 4Department of Pediatrics, Division of Neonatology, Baskent University Hospital, Adana, Turkey

**Background and Aim** A broad range of neurologic disorders have been described in children with Lyme disease. In contrast, there are few reports of transverse myelitis in pediatric Lyme disease patients.

**Case Report** A 12-old girl admitted with the complaints of weakness in legs, sensory loss in lower limb, and backache for 10 days. Mental status, cranial nerve, and upper-extremity motor and sensory examinations produced normal results. The strength in his ilio- psoas and hamstring muscles was scored 2/5. Deep tendon reflexes...
