were absent in both lower extremities. Babinski’s signs were not noted. The Romberg sign was present. Magnetic resonans imaging (MRI) of the spinal cord revealed enhancing T2 hyperintensity within the spinal cord, from T10-L1, (Figure 1). Cerebrospinal fluid (CSF) showed no pleocytosis and normal protein and glucose concentrations. The CSF did not show oligoclonal banding and immunoglobulin (Ig)G index was normal. Serum serologic evaluation of Borrelia burgdorferi was positive for IgM but negative for IgG. CSF serologic evaluation was negative (both ELISA and Western blot). The patient was diagnosed as manifesting acute transverse myelitis. He was treated with intravenous methylprednisolone pulse therapy (1000 mg/day for 5 consecutive days), followed by oral prednisolone (1 mg/kg per day). After the start of steroid therapy, the patient showed gradual clinical improvement and was able to walk on the 30th day of illness. We also administered doxycycline 4 mg/kg per day for 14-days for borreliosis.

**Conclusion** This case serves as a reminder that acute transverse myelitis can be a rare clinical manifestation of Lyme disease.

**Results** In the group receiving probiotics, mostly colonizing the stool cultures bacteria were Klebsiella spp, Escherichia coli, Enterococcus spp, Enterobacteriaceae spp, Staphylococcus spp respectively, and in the group not receiving probiotic mostly colonizing the stool cultures bacteria were Klebsiella spp, Enterococcus spp, Staphylococcus spp, Escherichia coli, Enterobacteriaceae spp respectively. When probiotic receiving group compared was with not receiving group, proliferation rate of stool cultures was higher in probiotic group. In the groups receiving and not receiving probiotic, proliferation of the nose cultures were similar. Increase in the proliferation rates of weekly stool cultures in probiotic receiving group was statistically significant but there was no statistically difference in the proliferation rates of nose and other cultures that were taken weekly. There was no statistical difference in both groups in the development of resistant organisms.

**Conclusions** The use of probiotics in neonatal intensive care unit for premature infants who received treatment with antibiotics, did not prevent the colonization of pathogenic microorganisms.

**Background** The empirical use of antibiotics in children with suspected meningitis is a common clinical practice worldwide that often leads to drug resistance. It is difficult to clinically differentiate bacterial when compared to viral meningitis until a culture study ofcerebral spinal fluid (CSF) Or CSF viral PCR study is performed. A ‘wait and see’ approach may lead to undesirable outcome. Bacterial Meningitis Score (BMS) is a tool that was developed to help physicians to differentiate between viral versus bacterial meningitis.

**Aim** To determine the usefulness if any of BMS for discriminating between bacterial or viral meningitis is young children.

**Methodology** We retrospectively reviewed the charts of all children (from birth till 14 years old) who were admitted with the diagnosis of meningitis to Hamad general hospital in last 2 years period.

**Result** A total 120 patients (68% boys) with confirmed viral meningitis were reviewed during the study period. The mean age was (6.3±2.7 year). The majority of patients 112 (93.3%) had viral type meningitis while the remaining had bacterial meningitis (Strep Pneumia, Neisseria meningitis and H. Influenza). The sensitivity of BMS tool revealed a sensitivity of 100% (95% CI: 75.1 to 100.0) and a specificity of 60.9% (95% CI:69.7).

**Conclusion** Our study shows that BMS is a simple, easy and highly sensitive tool that can differentiate bacterial from viral meningitis and it is use may limit the use of unnecessary antibiotics and hospitalizations.
2. Furthermore, to study the confound factors which increase the sensitivity of this test in order to reduce unnecessary culture of urinanalysis.

A total of eighty patients admitted to Pediatrics wards at Al-Adan Hospital over a period of four months were found to have a positive nitrite test in routine urinanalysis. only 38 (47%) were significantly positive (true bacterial growth of >= 100000 CFU/ml). Other studied confound factors such as fever, urinary symptoms, rigors, family history and past history of UTI, history of nocturnal enuresis or constipation were only significant if taken in combination (of those with positive urine cultures 97% had more than one factor). Urinary leukocyte count was significantly elevated (> 10/ hpf) in 90% of the patients with a positive urine cultures. Our data indicates that ordering urine culture in patients with a positive nitrite in urinanalysis should be restricted only to those who also have elevated urinary leukocyte esterase and those who have one or more risk factor for UTI.

836 DISTRIBUTION OF INTESTINAL PARASYTES IN A PEDIATRICS CLINIC IN 3 YEARS’ PERIOD

doi:10.1136/archdischild-2012-302724.0836

1M Ugras, 2O Miman, 3E Alpay. 1Pediatrics, Yeditepe Univ Medical Faculty, Istanbul; 2Microbiology, 3Pediatrics, Kocatepe University Medical Faculty, Akyonkarahisar, Turkey

Aim Intestinal parasitic infections are frequently seen in developing countries. Clinical findings such as abdominal pain, anal itching, salivation during sleep, and nasal itching are related with the prevalence of parasitic infection. The reported ranges from different cities in Turkey vary between 4.4% and 44.6%. We aimed to look for the prevalence of intestinal parasites in children who were brought to our clinic in a 3-years’ period.

Material and method The laboratory and clinical data of the children who were admitted to the Department of Pediatrics between January 2010 and December 2012 were retrospectively evaluated. Age, major complaint of the children were noted.

Results A total of 1790 stool samples were studied and 116 samples (6.48%) had intestinal parasites. There were 1712 children aged between 5 month and 17 years. The complaints were abdominal pain, failure to thrive and anal itching. Intestinal parasites were Giardia intestinalis 33 (1.84%), Blastocystis hominis 52 (2.9%), Enterobius vermicularis 13 (0.72%), Entamoeba coli 17 (0.95%), Mayca was found in 95 stool samples (5.3%). Multiple parasites were seen in 1 (0.05%) sample (Blastocystis hominis, Entamoeba coli).

Conclusion Intestinal parasites are frequently seen in developing countries. The mean vales are reported as 12%, 10% and 19% from different cities in Turkey between 2 and 6 years, all of them had fever, abdominal pain and constitutional syndrome. Three of them used to drink raw goat’s or cow’s milk. In 2 cases tuberculin skin test was over than 12 mm. There was open surgery (3) or laparoscopy (2) for realization of lymph node biopsy or drainage of abscess. The diagnosis was through culture and PCR in drained material and/or lymph node. Associated complications were: intraabdominal bacterial infection (4), enterococci fistula (2), intestinal occlusion (3). All patients were immunocompetent, except one case with histocompatibility complex II molecules deficiency. Empirical treatment consisted in isoniazid and rifampicin for 6 months, amikacin (3) or ethambutol (2) during 1 or 2 months respectively. One patient developed a Dress syndrome related to rifampicin. All patients received antituberculous drugs during 6 months, except two patients who needed extended therapy.

Conclusion Treatment for abdominal tuberculosis must be medical, and surgery should be used only in serious complications or biopsy. Although the clinical presentation is often very similar from the produced by M. tuberculosis, empirical therapy avoiding pyrazinamide should be started if MB is suspected.

837 VIEWS OF HEALTH CARE STAFF ABOUT PANDEMIC INFLUENZA VACCINE PRIOR TO PANDEMICS

doi:10.1136/archdischild-2012-302724.0837

1A Ozkaya-Parlakay, 1AH Abdulmumin, 2A Kara, 3AB Cengiz, 4E Ince, 5E Çiftçi, 6H Tezer, 2H Ozdemir, 3E Celiker. 1Pediatric Infectious Diseases, Hacettepe University, Faculty of Medicine; 2Pediatric Infectious Diseases, Ankara University; 3Pediatric Infectious Diseases, Ankara Hematology and Oncology Training Hospital, Ankara, Turkey

Pandemic influenza vaccine, is important in many aspects for health care staff. Our questionnaire was conducted in 3 different centers to evaluate view of health care staff for pandemic influenza vaccine prior to epidemics. Our questionnaire was conducted with health care workers having possibility of direct exposure to patients including 182 doctors, 158 nurses and 54 management staff with a total of 394 people. The center of the staff, position, period of Office, whether she/he had seasonal influenza vaccine, whether he/she plans to get pandemic influenza vaccine and reason for this was questioned and noted. Of the 394 healthcare staff included in our study 221 were working in Hacettepe University Hospital,102 were in Ankara University Hospital, 71 were in Ankara Hematology and Oncology Hospital. Of the people enrolled in our study 259 were planning to get pandemic influenza vaccine while 135 were not. Of the staff planning to get pandemic influenza vaccine 77.6% were planning because they thought they were in risk group, 22.4% were planning because there was pandemics. Of the staff not planning to get pandemic influenza vaccine 25% were not taking vaccine because they did not want be guinea pig, 30.9% were concerned with side effects of vaccine, 46% had concerns as vaccine was too new. In case of group vaccination declaration of the specialists and determination of health care authorities is very important, so declarations about vaccine should adhere to this aspect. Other wise even in risk groups acceptance of the vaccine would be in lower rates.

838 ABDOMINAL TUBERCULOSIS DUE TO MYCOBACTERIUM BOVIS

doi:10.1136/archdischild-2012-302724.0838

G Lozano Sánchez, E Núñez Cuadros, D Moreno Pérez, VM Candón Moreno, B Carazo Gallego, A Urda Cardona. Paediatric, Hospital Carlos Haya, Málaga, Spain

Background Currently, disease related to Mycobacterium bovis (MB) is rare in Spain (less than 1% of tuberculosis cases). However, it’s more frequent in undeveloped countries where the way to become infected is usually by raw milk consumption.

Methods We describe the epidemiologic, clinical and therapeutic characteristics of 5 patients with abdominal tuberculosis due to MB.

Results Five children (3 male) emanating from Morocco with ages between 2 and 6 years, all of them had fever, abdominal pain and constitutional syndrome. Three of them used to drink raw goat’s milk. In 2 cases tuberculin skin test was over than 12 mm. There was open surgery (3) or laparoscopy (2) for realization of lymph node biopsy or drainage of abscess. The diagnosis was through culture and PCR in drained material and/or lymph node. Associated complications were: intraabdominal bacterial infection (4), enterococci fistula (2), intestinal occlusion (3). All patients were immunocompetent, except one case with histocompatibility complex II molecules deficiency. Empirical treatment consisted in isoniazid and rifampicin for 6 months, amikacin (3) or ethambutol (2) during 1 or 2 months respectively. One patient developed a Dress syndrome related to rifampicin. All patients received antituberculous drugs during 6 months, except two patients who needed extended therapy.

Conclusion Treatment for abdominal tuberculosis must be medical, and surgery should be used only in serious complications or biopsy. Although the clinical presentation is often very similar from the produced by M. tuberculosis, empirical therapy avoiding pyrazinamide should be started if MB is suspected.

839 VIEW OF PREGNANT WOMEN ABOUT PANDEMIC INFLUENZA VACCINE PRIOR TO PANDEMA

doi:10.1136/archdischild-2012-302724.0839

1A Ozkaya-Parlakay, 2O Kara, 3A Kara, 2O Ozyuncu. 1Pediatric Infectious Diseases; 2Obstetrics and Gynecology, Hacettepe University, Faculty of Medicine, Ankara, Turkey

Afterwards pregnant women were detected to have serious complications with pandemic A (H1N1) virus in 2009, priority of their vaccination was accepted. Thus our study was planned to estimate the view of pregnant women about pandemic influenza vaccine to prevent disease admitting to a reference hospital having patients all
