Objective To evaluate the effect of slow versus rapid rates of advancement of enteral feed volumes upon the clinical outcomes in preterm infants with 750–1250g birth weight.

Study Design A total of 92 stable neonates with the birth weight 750–1250g and gestational age less than 32 weeks were randomly allocated to enteral feeding advancement of 20ml/kg/day (n=46) or 30ml/kg/day (n=46). The primary outcome was days to reach full enteral feeding defined as 180ml/kg/day. Secondary outcomes included rates of necrotising enterocolitis and culture-proven sepsis, days of total parenteral nutrition, length of hospital stay and growth end points.

Result Neonates in the rapid feeding advancement group achieved full enteral volume of feedings earlier than the slower advancement group. They received significantly fewer days of parenteral nutrition, exhibited a shorter time to regain birth weight and shorter duration of hospital stay. The incidence of NEC and the number of episodes of feeding intolerance were not significantly different between the groups while the incidence of culture-proven late onset sepsis was significantly less in infants receiving a rapid feeding advancement. Excluding infants who were small for gestational age at birth, the incidence of extraterine growth restriction was significantly reduced in the rapid advancement group at 28 days and at hospital discharge.

Conclusion Rapid enteral feeding advancements in 750–1250g birth weight infants reduces the time to reach full enteral feeding and the use of TPN administration. Rapid advancement enteral feed also decreases extraterine growth restriction with improved short-term outcomes for these high-risk infants.

Background Fat emulsions used in Australia for PN in preterm neonates have been based on either soybean oil (SO) or olive oil (OO). OO based lipid Clinoleic has high ratio of n-6 to n-3 fatty acids (9:1) this may not be ideal for LC-PUFA supply. Newly available SMOflipid has appropriate ratio n-6 to n-3 fatty acids (2.5:1). SMOflipid also contains OO (25%), coconut oil (50%) and SO (30%). Better lipid clearance, reducing the risk of liver toxicity, reduced oxidative stress, lower immune-activity and anti-inflammatory effects are other potential advantages of SMOflipid.

Method Preterm neonates (26–30 weeks) were randomised to receive Clinoleic or SMOflipid emulsion for 7 days using a standard protocol. Investigators and outcome assessors were masked to allocation. Plasma F_{2}-isoprostanes (lipid peroxidation marker), RBC fatty acids, vitamin-E were measured before and after the study. Blood culture positive sepsis and growth was monitored for safety.

Results 80/84 participants (Clinoleic-15, SMOflipid-15) completed the study. Both emulsions were well tolerated without any adverse events. F_{2}-isoprostane levels were reduced in SMOflipid group as compared to baseline. Eicosapentanoic acid (EPA) and vitamin-E levels were significantly increased in SMOflipid group. Oleic and Linoleic acid levels were increased in both groups. No significant differences were noted in post study Docosahexaenoic acid (DHA) levels in both groups despite higher levels of DHA in SMOflipid.

Conclusions SMOflipid was safe, well tolerated and also showed beneficial effect in terms of reduction of oxidative stress by reducing lipid peroxidation levels in high risk preterm neonates.
Early Postnatal Changes in Splanchnic Circulation in Healthy Term Newborns

Objective To characterize hemodynamic changes in celiac artery (CA) and superior mesenteric artery (SMA) in healthy term newborns during the first six hours after birth by means of Doppler ultrasonography.

Materials and methods The study included 30 healthy term newborns. The ultrasound examinations using Aloka α-10 were performed at the age of 2.4 and 6 hours after birth. The statistical analysis of Doppler variables was performed using the non-parametric Friedman test with all pairwise multiple comparisons. Presented results are shown as median (interquartile range).

Results A reversed blood flow in SMA, documented by negative values of end diastolic velocity (EDV) [-10.90 cm.s⁻¹ (-13.21–0.00)], changed to positive during the first six hours after birth (7.08 cm.s⁻¹ (6.29–15.48), p<0.001). In CA, EDV increased in this period, but negative values were not recorded (11.83 cm.s⁻¹ (9.34–13.86) and 18.03 cm.s⁻¹ (14.20–27.57)).

Conclusion Dramatic changes occur in splanchnic circulation during the first six hours after birth. In superior mesenteric artery, the negative diastolic blood flow turns to positive as a part of circulatory transition in the presence of a ductal steal.

Survival of Very Preterm Children Born in 2011: First Results of the EPIPAGE 2 Cohort Study

Aims The number of neonates born preterm is increasing and children born at low gestational ages face a range of risks. We present the first results of the EPIPAGE 2 study, a national cohort of very and moderately preterm children in France.

Methods EPIPAGE 2 is a prospective population-based cohort study conducted in 25 regions of France in 2011 including extremely (22–26 weeks, 8-month recruitment), very (27–31 weeks, 6-month recruitment) and moderately preterm (32–34 weeks, 1-month recruitment) children. It aims to examine short and long term outcomes (survival, health and development) of these children and their determinants. Data on pregnancy, delivery, and neonatal events were extracted from the obstetric and neonatal records.

Results A total of 5565 births were included in the EPIPAGE 2 study: 1752 were born extremely preterm (89% (51%) stillbirths and 54% (9%) live births), 2728 very preterm (29% (11%) stillbirths and 2430 (89%) live births), and 1085 moderately preterm (28 (2.5%) stillbirths and 1057 (97.5%) live births). The survival rates for extremely preterm babies were 23% of all births and 48% of live births. The corresponding survival rates were respectively 83% and 93% at 27–31 weeks and 96% and 99% at 32–34 weeks. In 1997 (EPIPAGE 1 study), the survival rates were 20% of all births and 46% of live births at 22–26 weeks and 76% of all births and 88% of live births at 27–31 weeks.

Conclusion Survival has improved among very preterm children, but has not changed at extremely low gestational ages.

Altered Fronto-Temporal Neuroanatomy in Very Preterm Born Adults During Completion of a Verbal Fluency Task

Background and aims Several studies have described poorer cognitive performance in various aspects of language such as comprehension, naming, expressive language and verbal fluency in individuals who were born very preterm compared to controls. Neuroimaging investigations have also described structural and functional changes that could underlie such language deficits. In this pilot study we used functional MRI to explore whether alterations in the neuroanatomy of phonological verbal fluency persisted into adulthood following very preterm birth.

Methods Twenty-two young adults (26–38 years old, females=11, males=11) were examined. Eleven individuals were born very preterm (gestational age: <38 weeks) and 11 were full-term born controls. All participants underwent functional MRI using a 3T scanner while completing a phonological verbal fluency task. All data pre- and post-processing was performed using FSL (www.fmrib.ox.ac.uk/fsl).

Results During successful verbal fluency trials, very preterm-born individuals showed significantly decreased blood-oxygen-level-dependent signal compared to controls in several brain areas including the orbitofrontal/medial frontal cortex bilaterally (x=8mm, y=52mm, z=−28mm) and the left fusiform/parahippocampal gyrus (x=−34mm, y=−30mm, z=−24mm), p<0.05 family-wise-error corrected (FWE). On-line performance did not significantly differ between the groups.

Conclusions Previous studies with functional MRI in younger samples have shown neuroanatomical alterations (increased and decreased activation) in fronto-temporal and fronto-striatal networks in very preterm born individuals when performing different cognitive tasks. Our results suggest that neuroanatomical alterations during language processing persist into adult life following very preterm birth, and specifically involve fronto-temporal networks, with important implications for a wide range of high order cognitive functions.

Neonatal Cerebral Oxygenation is Associated with Neurodevelopmental Outcome of Preterm Infants at 2 to 3 Years of Age
