between intrauterine growth inhibition and NO activity in late preterm infants.

**Methods** Newborns with gestational age of 34–36 weeks and birth weight of 1200–2600 g were allocated to two groups: 21 infants with normal growth parameters were classified as first group and 15 intrauterine growth restricted (IUGR) infants were included in second group. Gestational age was asessed by the last menstrual period and confirmed by scale of Ballard et al. Plasma and urine samples of infants were collected on the first day of life. Nitric oxide concentration quantified by principle based on using the enzyme Nitrate Reductase to convert nitrate to nitrite. Results Mean plasma nitrat products were higher (p<0.05) in second group infants (42.6±7.3 µM/L), than in first group (59±7.3 µM/L). Statistically true rising (p<0.01) was noted in urine NO level of IUGR infants, where mean NO level was 1.4 times higher compared with first group newborns.

**Conclusion** Intrauterine growth retardation is associated with high NO production of infants at an early neonatal period, which might indicate intrauterine activation of NO sources of fetus.

**1043 EVALUATION OF PEDIATRIC TESTES AFTER SURGERY BY LASER DOPPLER AND WHITE LIGHT SPECTROSCOPY**

**Aim** To evaluate testes after unilateral orchiopexy: Laser Doppler and white light spectroscopy and compare microcirculation with contralateral testis and healthy controls.

**Methods** A combination of the laser Doppler (determination of blood flow) and white light spectroscopy (determination of oxygen saturation and hemoglobin amount) is used to determine microcirculation at two different depth levels non-invasively. Patients were recruited after unilateral orchiopexy. Controls were age-matched boys without relevant disease. Ethical approval was obtained.

**Results** 99 patients were included after unilateral orchiopexy at the age of 3.5 years (+2.9 years). 65% underwent surgery after their second birthday. Follow-up was at median 2.5 years after surgery (3 months – 10.5 years). Controls were 29 boys at the age of median 6.3 years (3 month–13 years). There was no significant difference in age between both groups.

85 patients were examined on the operated side with laser doppler and white light spectroscopy. Significant higher flow and velocity were found contralateral (p=0.041, p=0.022). Surprisingly, when comparing the contralateral testes in patients after orchiopexy with healthy controls, flow and velocity were significantly higher in the healthy controls (p<0.001), even though this testis was previously not operated on.

**Conclusion** After orchiopexy, expected differences were found in microcirculation between the operated and contralateral testes or healthy controls. Surprisingly, the contralateral testes’ microcirculation was also significantly different from controls. This is probably not a consequence of surgery alone, but more likely a common problem of both testes in the affected patients.

**1044 EVALUATING MODE OF DELIVERY OF IRON OR IRON AND ZINC ON IRON STATUS AND IRON STRESS MARKERS**

**Background** Iron deficiency remains a major nutritional problem among infants and young children in India. The tablet/syrup-based programs do have logistic, supply and compliance challenges. Tablet/Syrup may have increased risk of free iron in blood, oxidative stress and risk of infections.

**Objective** In a community based RCT we evaluated 3 approaches of iron delivery for impact on iron status, pro and anti-inflammatory interleukins and non-transferrin bound iron (NTBI) with 30 day intervention.

**Methods** 300 children 22–34 months were enrolled and randomized to receive either iron fortified biscuit (n=74), iron tablet (n=77), iron+ zinc tablet (n=74) or placebo (n=75) for 30 days.

**Results** Delivery of iron through biscuit showed better impact on hemoglobin (Mean Diff: 0.60; 95 % CI: 0.16–0.10) and other hematological markers like RDW, MCV and MCH at 30 day post supplementation. The NTBI estimation at day 1 and 30 post supplementation, 3 hours after ingestion of supplement dose; an indicator of oxidative stress caused by dose after iron status relapse, suggested the lowest burden with biscuit (2 %) and a higher burden with supplements (6–7 %). At day 30 there was no effect on interleukins in the biscuit group; increase in IL-6/IL10 in iron tablet, increase in IL-5/IL10 in iron+ zinc tablet group.

**Conclusion** Providing iron through fortified biscuits was as efficient and effective in improvement of iron status and hematological markers as iron tablets. Biscuit was marginally better for NTBI or immune response. The benefit of using biscuits needs to be evaluated in a larger community based effectiveness program.

**1045 LONGITUDINAL STUDIES OF BREAST MILK ZINC TRANSFER TO APPROPRIATE- AND SMALL-FOR-GESTATIONAL-AGE, PREDOMINANTLY BREAST FED, BANGLADESHI INFANTS**

**Background** In developing countries, information is limited on concentration of breastmilk zinc, total amount of zinc transferred to infants through breast milk and whether zinc transfer through breastmilk differs among appropriate-for-gestational-age (AGA) and small-for-gestational-age (SGA) infants at different times post-partum.

**Aims** To measure breastmilk and zinc transfer through breastmilk, using deuterium “dose-to-mother” technique, in mothers of AGA and SGA infants.

**Methods** Forty-six mother-infant pairs were recruited (20 AGA and 26 SGA infants). Each mother-infant pair was studied three times, at 4, 12 and 24 weeks post-partum. In each round, two-week studies of breast milk transfer were carried out, using the deuterium oxide “dose-to-mother” technique. Breast milk samples were collected on days 1 and 5 of each round for milk zinc concentration.

**Results** Mean (±SD) birth weight and length were 3.02±0.2 kg and 48.2±1.2 cm for AGA infants and 2.34±0.20 kg and 46.2±1.1 cm for SGA infants. Breast milk intake increased gradually with time post-partum, and was marginally greater among AGA infants only at 4 weeks (p=0.06). Breast milk zinc concentration decreased when the infants grow (p<0.001), but differed between neither of the groups. Zinc transfer through breast milk decreased significantly with age in both the groups, but did not differ (p<0.001).

**Conclusions** Breast milk zinc concentration among Bangladeshi mothers was similar to values reported for women from wealthier countries, and there was no relationship between infant birth weight category and milk zinc concentration or milk zinc transfer.

**1046 IODINE STATUS IN PRESCHOOL CHILDREN AND EVALUATION OF MAJOR DIETARY IODINE SOURCES: A GERMAN EXPERIENCE**

**Background** Iodine deficiency is a global health problem affecting more than 2 billion people. Despite iodine supplementation programs, iodine deficiency still persists in many countries. It is also a major cause of preventable intellectual disability. In this study, we evaluated iodine status in preschool children and the contribution of dietary iodine sources to their intake.

**Methods** A cross-sectional study was conducted in 2012 in children aged 3–5 years from four German cities. Dietary iodine intake was assessed using a 24-hour recall method. Urinary iodine concentration was measured using an ion-selective electrode.

**Results** The median urinary iodine concentration was 155 µg/L, which is within the adequate range. The main dietary sources of iodine were seafood, dairy products, and bread. The contribution of each source to total dietary iodine intake was calculated.

**Conclusions** Iodine deficiency is not a major public health concern in preschool children in Germany. However, further efforts are needed to ensure adequate iodine intake in this population.
Abstracts

SA Johner, T Remer. DONALD Study, University of Bonn, Research Institute of Child Nutrition, Dortmund, Germany

Purpose Even mild iodine deficiency may negatively affect cognitive performance, especially at a young age. Our aim was to investigate iodine status in very young children and to assess the importance of iodized salt in processed foods as an example for a country with voluntary salt iodization.

Methods 24-h urinary iodine excretion (UIE) as a marker of iodine intake was measured in 578 repeatedly collected 24-h urine samples (2003–2010) of 221 3–6 year old participants of the DONALD Study. Parallel 3-d weighed dietary records and measurements of urinary sodium excretion provided data on the daily consumption of the most important iodine providers in the children’s diet (iodized salt, milk, fish, meat and eggs). Time trends of UIE (2003–2010) and contributions of the different food groups were analysed by using linear mixed-effects regression models.

Results Median UIE of 71 µg/d in boys and 65 µg/d in girls, corresponding to an iodine intake of 82 and 75 µg/d, respectively (assumption: 15% non renal iodine losses) was below the WHO intake recommendations of 90 µg/d. Milk, salt and egg intake were significant predictors of UIE; milk and salt together accounted for >80% of iodine supply. Between 2003 and 2010, UIE decreased significantly by approximately 1 µg/year. The contribution of salt intake to UIE decreased from 03–06 to 07–10.

Conclusion In countries where salt is a major iodine provider, already modest decreases in the iodized proportion of salt used in processed foods may relevantly impair iodine status even in preschool children.

1049 BURDEN OF CHRONIC EXPOSURE TO DIFFICULT ETHICAL DECISIONS ON CAREGIVERS IN SWISS NICUS

N Hauser, HU Bucher, JC Fauchere. Division of Neonatology, Univ. Hospital Zurich, Zurich, Switzerland

Aim This study explored the degree of burden of chronic exposure to difficult ethical decisions on care providers (HCP) in Swiss level III NICUs.

Methods 224 questionnaires were sent to neonatologists and nurses of all level III NICUs. Demographical information, attitudes and behaviours towards ethical decisions, and the impact of those decisions on HCP’s health and private life were collected.

Results 52 neonatal physicians and 60 nurses (27 men, 85 women, overall response rate 50%) took part in this survey. Altogether, 78% stated that the ethical dilemmas/decision-making represent a burden to them. 87% experience this burden as momentary. In nearly 40%, this burden affects private life; in another 48% it occasionally impact on private life. 25% of physicians and 10% nurses suffer from exhaustion. Most of the respondents find relief from stress through their hobbies (70%) and discussions with family members and friends (74%). The most used coping strategies are debriefings after ethical discussions, team discussions and support from hospital pastoral care. Professional moderation of debriefings was only rarely available (10%).

Conclusion Chronic exposure to stressful situations represents a burden for the majority of HCP working in NICU environment. Exhaustion is far more frequent than physical and psychosomatic symptoms. Hobbies and social contacts are important coping strategies. Given the potential of chronic burden to not only affect health of caregiver but also to shape the attitudes of caregivers in daily neonatal intensive care medicine, the importance of team debriefings and support under professional guidance cannot be stressed enough.
