Methods
Newborn piglets underwent hypoxia following a standardized model. They were randomly assigned for 30 min resuscitation with air (21% O2) (n=12) or 2.1% Hydrogen gas mixed into synthetic air, H2 (n=14) and then observed for 9 hours. One control group (n=6) went through the same procedures and observation time (anesthesia, surgery, ventilation and sample collection). The left hemisphere was used for histopathology. Tissue from prefrontal cortex and liver were snap frozen in liquid nitrogen and stored by -70°C until analysis. The tissue samples were homogenized and the protein extracted. A Quantikine KM 300 immunoassay was used to measure activated caspase-3 protein. Gene expression for Casp-3, BDNF, MMP-2, MMP-9 and VEGFR2 was measured in tissue from prefrontal cortex and liver.

Results
The use of 2.1% hydrogen gas mixed into synthetic air decreased activated caspase-3 vs. air. In liver tissue piglets resuscitated with air: 12.6 pg/mg protein SD (9.1) vs. H2: 5.3 (4.9), p=0.031 whereas in cortex piglets resuscitated with air 26.3 pg/mg protein (14.9) vs. H2 15.4 (13.0), p=0.05.

There were no significant changes in gene expression in liver and cortex. Histopathology showed a tendency to less brain damage in the hydrogen group.

Conclusions
Hydrogen gas used for newborn resuscitation may reduce apoptosis.

A1115 THE NEUROPROTECTIVE EFFECTS OF VALPROIC ACID, AN HISTONE DEACETYLASE INHIBITOR IN A NEONATAL HYPOXIC-ISCHEMIC RAT MODEL
doi:10.1136/archdischild-2012-302724.1115

Introduction Neurodegenerative diseases were associated with a decrease in histone acetylase transferase (HAT) activity, resulting in relative over-deacetylation. Histone deacetylase (HDAC) inhibitors were suggested as potentially neuroprotective agents. The aim of this study was to evaluate the neuroprotective effects of valproic acid (VPA), an histone deacetylase inhibitor, in neonatal hypoxic ischemic rat model.

Methods
After being anesthetized, 7-day-old pups underwent ischemia followed by exposure to hypoxia. The pups were divided into 3 groups: sham group, vehicle group (saline group) and VPA group. VPA was administered intraperitoneally for three times; the first just after hypoxia-ischemia, the second and the third doses 24 and 48 hours after the first dose, respectively. After sacrifice, brain infarct volume, apoptosis, HDAC activity, acetylated H4 protein and caspase 3 expression, and proinflammatory cytokine concentrations were evaluated in brain tissue of rat pups.

Results
Percent infarcted brain volume and number of TUNEL positive cells per unit area in hippocampus and cortex CA1 were markedly reduced with VPA treatment. HDAC activity was found to be significantly reduced in VPA group, whereas acetylated H4 protein expression was significantly increased with VPA treatment. The caspase-3 activity in VPA group was significantly lower than the control group. The proinflammatory cytokine levels also significantly decreased with VPA treatment.

Conclusion This is the first study that showed the neuroprotective effects of VPA treatment as an HDAC inhibitor by reducing percent infarcted brain volume, histone deacetylase activity, inflammation and apoptosis while increasing acetylated H4 protein levels in a neonatal hypoxic-ischemic rat model.

A1116 HYPERGlyCAEMIA AND INSULIN-INDUCED ALTERATIONS IN THE RETINA OF RAT PUPS
doi:10.1136/archdischild-2012-302724.1116

Background and Aims Rat pups are applicable to investigate specific role of the factors which are implicated in the pathogenesis of retinopathy of prematurity (ROP) including hyperglycaemia and insulin treatment.

Methods
The aim of our study was to investigate specific effect of streptozotocin-induced hyperglycaemia, insulin-treatment and intravitreal injection of a potential retinoprotective agent, pituitary adenylate cyclase activating polypeptide (PACAP) on the rat pup’s retina. We made a comparative analysis between the following treatment-groups: controls (Stz-/Ins-), insulin-treated (Stz-/Ins+), hyperglycaemic (Stz+/Ins-), insulin-treated hyperglycaemic (Stz+/Ins+), all animals were treated with intravitreal PACAP or vehicle. Blood glucose levels were monitored. The retinas were processed on P21 for routine histology and immunohistochemistry for glial fibrillary acidic protein (GFAP), GLUT1 and tyrosine hydroxylase (TH).

Results
Standard histological methods revealed no major differences between the groups. Elevated expression of GFAP – as an specificity of metabolic insults in the retina- was detected from the inner retina in the Stz-/Ins- group, although hypoglycaemia didn’t develop. Similar alteration of the GFAP staining was found in the hyperglycaemic (Stz+/Ins-) and insulin-treated hyperglycaemic (Stz+/Ins+) groups. Intravitreal PACAP resulted in suppression of the elevated GFAP expression in the Stz-/Ins- group, but not in the Stz+/Ins- and Stz+/Ins+ ones. None of the groups showed alterations in the anti-TH immunoreactivity (dopaminergic amacrine cells) or GLUT1 expression of pigment epithelial cells.

Conclusions
In our model hyperglycaemia or insulin did not induce ROP; however, sign of metabolic insult was detected in the neural retina, which was partly prevented by intravitreal PACAP application.

A1117 A PIG MODEL OF THE PRETERM NEONATE: ANTHROPOMETRIC AND PHYSIOLOGICAL CHARACTERISTICS
doi:10.1136/archdischild-2012-302724.1117

1YA Elby, 1L Wright, 1ER Lumbergs, 2R Coldt, 2B Lingwood. 1UO Centre for Clinical Research, The University of Queensland, Brisbane, QLD; 2Mothers and Babies Research Centre, Hunter Medical Research Institute, Newcastle, NSW, Australia

Background and Aims
Large animal models are an essential research tool to investigate the physiology of the preterm infant, which remains poorly understood. We aim to describe the pig model of the preterm neonate in terms of growth, maturation and requirement for intensive care over a range of gestational ages and determine the effects of maternal glucocorticoid exposure and sex.

Methods
Twenty-nine litters of piglets (N=260) were delivered by C-section at 91d, 94d, 97d, 100d, 104d and 113d (term 115d). Some litters received maternal betamethasone treatment (0.19mg/kg body wt; 1M) at 48h and 24h prior to delivery. At 97d piglets were resuscitated, surfactant administered, and piglets were ventilated, sedated and monitored for 6-8h post-born using standard NICU techniques.

Results
At 91d, piglets were half the weight of term animals, had fused eyelids, very thin skin, no hair, and survived a maximum of 5h due to difficulties with ventilation. At 97d piglets were able to be maintained for at least 6-8h but physiology was unstable for 1-2h. Piglets 100d and older breathed spontaneously. Only near term piglets were able to maintain body temperatures. Males were heavier than females at 113d gestation (p=0.021). Exposure to maternal glucocorticoids resulted in larger females and influenced brain:body wt. Piglets allowed for parallel experiments or the use of littermates as controls.
