Background FHHNC is a rare autosomal recessive tubulopathy of the thick ascending limb due to inactivating mutations in the Claudin-6 and Claudin-19 genes which are responsible for the paracellular reabsorption of calcium and magnesium. Clinically, FHHNC is characterized by urinary tract infections, nephrolithiasis, nephrocalcinosis and progressive renal failure.

Objective To present clinical and molecular data on 2 siblings with FHHNC and early onset SND, found to have a new mutation in the Claudin-6 gene.

Methods A 16-year-old male and his 14-year-old sister were diagnosed with chronic kidney disease since early infancy, manifested by recurrent UTIs, polyuria and polydipsia, poor growth, mild mental retardation and delayed speech. SND was diagnosed at the age of 6 and 7 years. Both have hypomagnesemia, hypermagnesuria, hypercalciuria and nephrocalcinosis. Genotyping was performed by PCR using tetranucleotide repeat polymorphisms. Specific primer pairs of genomic DNA were used as template for sequencing the Claudin6 gene.

Results Exons 1, 2, 4 and 5 were amplified and revealed wild type sequencing but exon 3 failed in amplification by PCR. Long range PCR spanning exon 2 to 4 of the gene yielded a 2.5 kb fragment shared by the patients. Sequencing of this fragment revealed a 2630 bp deletion including the entire exon 3 resulting in deletion and frame shift of Claudin6 protein.

Conclusion This family demonstrates the first identified homozygous mutation in the Claudin6 gene causing the deletion of an entire exon. This, however, is unlikely to explain the SND, since this gene is not expressed in the cochlea.

Abstract 1203 Figure 1

Conclusions ODM have higher SBP than controls. This increase is independent of type of maternal diabetes and may be related to maternal pre-pregnancy BMI. Gender-specific differences require further investigation.

Utility of Serum Procalcitonin to Predict Renal Scars in Infant with Febrile Urinary Tract Infection

Background and Aims The aim of this study was to evaluate the usefulness of Procalcitonin (PCT) as a marker for renal scars in infants with a first febrile urinary tract infection (UTI). DMSA scintigraphy, the gold standard for detection of cortical scarring, has clearly shown that not all febrile UTI are associated with renal lesions and that common clinical and laboratory evaluations are not reliable to distinguish between acute pyelonephritis (APN) and simple UTI. Scarring secondary to APN is a common event occurring in approximately 30% of all cases.

PCT, prohormone of calcitonin has been measured in various systemic inflammatory response syndromes, because it appears to be correlated with the severity of microbial invasion and it can be used to check for the presence of parenquimal scars.
Methods This prospective study includes 140 children less than 2 years, 64% females admitted for febrile UTI. PCT levels were measured at diagnosis and DMSA scan at the 6 months. We use a study of diagnostic test assessing their sensitivity and specificity. ROC curve was performed.

Results Abnormal DMSA was found in 14 infants (11.3%). Using a cutoff value of 0.6ng/ml. PCT sensitivity for detect renal scars on DMSA was 57.1% (95%CI, 31.2–83.1%) and specificity was 56.1% (95%CI, 46.7–65.5%). Negative predictive value was 90.9% (95%CI, 84–97.8%). AUC (area under curve) is 0.582.

Conclusions We can conclude that PCT yields a high negative predictive value of renal damage. Therefore a low PCT value at the time of admission points out a low risk of renal scarring.

INCIDENCE OF ACUTE POST STREPTOCOCCAL GLOMERULONEPHRITIS IN CHILDREN

doi:10.1136/archdischild-2012-302724.1205

1MM Begoli, 2M Begoli. Nephrology, Pediatric Clinic, University Clinical Centre of Kosovo; 2Social Medicine, Medical Statistic and Informatic, University of Prishtina, Pristina, Kosovo

Aim To present a number of children with set diagnosis of APSGN in the Pristina Children’s Clinic, incidence, clinical characteristics of the disease an treatment. Their follow up aimed to determine the further course of the disease and the possibility for progressing into a chronic form.

Materials and Methods This was an analysis of the children treated in the Pristina Children’s Clinic during 2009–2011. General date has been taken from all hospitalized patients, including: age, gender, parent’s profession, residence and dwelling condition. The diagnosis of APSGN was set in 98 children based an anamnestic date for existing a prior streptococcal infection, characteristic clinical picture, as well as laboratory analyses (hematuria, proteinuria, titer of ASO, determination of the serum creatinin and urea and concentration of C3 and C4).

Results From 98 patients, witch is the total number of the examinees, the majority belonged to the 7–11 year old group, will the male patients were more frequent. According to the obtain anamnestic date, 82% cases had and anticipatory throat infection. In all cases, the clinical symptoms were hematuria and/or proteinuria. Hypertension was present in 73% cases, while edema was confirmed in 79% of the hospitalized patients. Positive ASO titer was confirmed in 75.8% cases.

Conclusion In a larger number of our patients, i.e. in 96.5 % a complete recovery was obtained with further ambulence follow up, and only 3.5% entered into the form of chronic glomerulonephritis.

ASSOCIATION BETWEEN DIFFERENT ACUTE KIDNEY INJURY (AKI) DEFINITIONS AND MORTALITY IN VERY LOW BIRTH WEIGHT (VLBW) INFANTS

doi:10.1136/archdischild-2012-302724.1206

Background AKI has been associated with increased mortality rate among VLBW infants. The best creatinine-based definition for AKI is still unclear. Our aim was to correlate mortality and different AKI-definitions.

Methods From January 1st 2005 to December 31st 2011 all VLBW infants born at S. Gerardo Hospital were recruited whenever ≥2 consecutive p-creatinine determined within 48 hours between 3 and 15 days of life were available.

AKI was defined as single creatinine ≥2.5 mg/dl (AKI-1), increase of ≥4.0 mg/dl within 48h (AKI-2) or increase of ≥50% within 48h (AKI-3).

The statistical concordance between the definitions was evaluated using the Cohen’s Kappa coefficient and their association with mortality using uni- and multivariable logistic regression. AKI-definitions were adjusted for each other and for GA, BW and Apgar score.

Results Among 263 VLBW infants, 28 (10.6%), 40 (15.2%) and 26 (9.9%) met the definition for AKI-1, AKI-2 and AKI-3 respectively. Low agreement was shown between AKI-1/AKI-2 (Kappa 0.48, 95%CI:0.27–0.59) and AKI-1/AKI-3 (Kappa 0.52, 95%CI:0.14–0.51). Substantial agreement was observed for AKI-2/AKI-3 (Kappa 0.69, 95%CI:0.56–0.82).

68/263 patients died (28.8%), with AKI-1 45.1%, AKI-2 52.5% and AKI-3 26.9% respectively.

AKI patients run higher risk of death than the others (Crude OR 15.6 [P<0.001], 6.7 [P<0.001] and 3.8 [P<0.007] for AKI-1, AKI-2 and AKI-3).

Using multivariable model, AKI-1 and AKI-2 remained associated with higher mortality (OR 4.25 [P=0.008] and OR 3.70 [P=0.041]).

Conclusions Different AKI-definitions lead to substantially different patients classifications. Even minimal increment of creatinine are associated with augmented risk of death among VLBW infants.

TREATMENT AND DIAGNOSIS OF THE NEPHRITIC SYNDROME IN CHILDREN

doi:10.1136/archdischild-2012-302724.1207

1AY Naushabayeva, 2BA Abeuova, ‘G Chingayeva, ‘A Narbekova, ‘K Kabulbayev, ‘AB Kurgibekova. Nephrology, The Kazakh National Medical University, Almaty; Pediatrics and Neonatology, Karaganda State Medical University, Karaganda; Endocrinology, The Kazakh National Medical University, Almaty, Kazakhstan

Background and Aims Nephritic syndrome (NiS) is of significant concern in Pediatric Nephrology with high progression rate. Aim of our study was to establish the pathohistological pattern, and assessment of mofetil mycophenolate efficacy (MMP) in comparison with cyclophosphamide (CYC) in children with NiS.

Methods Study was conducted in 27 children (16 boys) with chronic NiS. Kidney biopsy was performed in all patients under US-guidance using biopsy gun. Pathohistological investigation of renal biopsy included: light, immunofuorescent and electron microscopy.

Results Most frequent pathohistological variant was IgA- nephropathy (IgA-NP) (74.1%, p<0.001). In 14.8% patients NiS was associated with hereditary nephritis. Membranoproliferative glomerulonephritis (GN) (3.7%), and extracapillary GN (3.7%) were observed rarely. To induce the remission we used IV methylprednisolone for 3–6 days, oral prednisolone (Pred) 60 mg/m²/day, MMP 1 g/m²/day for 3–4 months. Remission was established when proteinuria was decreased to 0.5 g/day. Maintenance therapy was administered for one year or longer. Controls were administrated with IV (5–4 pulses) or oral (for 2 months) CYC, Pred 60 mg/m²/day for 1.5–2 months with following alternating schedule. All patients have received ACE inhibitors. Proteinuria was significantly (p<0.05) lower in main group (0.1 g/day) in comparison with controls (0.9 g/day), and GFR increasing was more prominent in main group (from 68.5 to 98.1 ml/min/1.73m²), than in controls (from 68.5 to 59.1 ml/min/1.73m²) (p<0.05).

Conclusions Thus, chronic nephritic syndrome in children was mostly associated with IgA-nephropathy. Combination treatment with mycophenolate mofetil + steroids and ACE inhibitors is more effective and safe than cyclophosphamide treatment.
