Background FHHNC is a rare autosomal recessive tubulopathy of the thick ascending limb due to inactivating mutations in the Claudin-16 and Claudin-19 genes which are responsible for the paracellular reabsorption of calcium and magnesium. Clinically, FHHNC is characterized by urinary tract infections, nephrolithiasis, nephrocalcinosis and progressive renal failure.

Objective To present clinical and molecular data on 2 siblings with FHHNC and early onset SND, found to have a new mutation in the Claudin-16 gene.

Methods Exons 1, 2, 4 and 5 were amplified and revealed wild type sequencing but exon 3 failed in amplification by PCR. Long range PCR spanning exon 2 to 4 of the gene yielded a 2.5 kb fragment shared by the patients. Sequencing of this fragment reveal a 2650 bp deletion including the entire exon 3 resulting in deletion and frame shift of Cldn16 protein.

Conclusion This family demonstrates the first identified homozygous mutation in the Cldn16 gene causing the deletion of an entire exon. This, however, is unlikely to explain the SND, since this gene is not expressed in the cochlea.

Abstract 1203 Figure 1

Conclusions ODM have higher SBP than controls. This increase is independent of type of maternal diabetes and may be related to maternal pre-pregnancy BMI. Gender-specific differences require further investigation.

Background and Aims Offspring of diabetic mothers (ODM) are at increased risk of the metabolic syndrome in later life. We aimed to perform a systematic review and meta-analysis of studies examining offspring systolic and diastolic blood pressure (SBP, DBP) in childhood in relation to maternal diabetes.

Methods Citations were identified in PubMed. Authors were contacted for additional data where necessary. SBP and DBP in ODM and controls were compared. Subgroup analysis was performed according to type of maternal diabetes and offspring gender. A fixed effect meta-analysis was performed, and a random effects analysis where significant heterogeneity was present. Meta-regression was used to test the relationship between offspring SBP and maternal pre-pregnancy BMI.

Results Fifteen studies were included in the systematic review and thirteen in the meta-analysis. SBP was 1.88mmHg higher in ODM (95% CI 0.47, 3.28; p=0.009). The increase in SBP was similar in both offspring of mothers with gestational diabetes (1.39mmHg [0.00, 2.77]; p=0.05) and type 1 diabetes (1.64mmHg [0.09, 3.18]; p=0.04). Male ODM had higher SBP (2.01mmHg [0.93, 3.10]; p=0.0003) and DBP (1.12mmHg [0.36, 1.88]; p=0.004) than controls, but the differences in SBP and DBP between female ODM and controls were not statistically significant. Offspring SBP was positively correlated with maternal pre-pregnancy BMI; however, the association was not significant (p=0.37).

Utility of Serum Procalcitonin to Predict Renal Scars in Infant with Febrile Urinary Tract Infection

Background and Aims The aim of this study was to evaluate the usefulness of Procalcitonin (PCT) as a marker for renal scars in infants with a first febrile urinary tract infection (UTI).

DMSA scintigraphy, the gold standard for detection of cortical scarring, has clearly shown that not all febrile UTI are associated with renal lesions and that common clinical and laboratory evaluations are not reliable to distinguish between acute pyelonephritis (APN) and simple UTI. Scarring secondary to APN is a common event occurring in approximately 30% of all cases.

PCT, prohormone of calcitonin has been measured in various systemic inflammatory response syndromes, because it appears to be correlated with the severity of microbial invasion and it can be used to check for the presence of parenquimal scars.
Methods This prospective study includes 140 children less than 2 years, 64% females admitted for febrile UTI. PCT levels were measured at diagnosis and DMSA scan at the 6 months. We use a study of diagnostic test assessing their sensitivity and specificity. ROC curve was performed.

Results Abnormal DMSA was found in 14 infants (11.3%). Using a cutoff value of 0.6ng/ml. PCT sensitivity for detect renal scars on DMSA was 57.1% (95%CI, 31.2–83.1%) and specificity was 56.1% (95%CI, 46.7–65.5%). Negative predictive value was 90.9% (95%CI, 84–97.8%). AUC (area under curve) is 0.582.

Conclusions We can conclude that PCT yields a high negative predictive value of renal damage. Therefore a low PCT value at the time of admission points out a low risk of renal scarring.

INCIDENCE OF ACUTE POST STREPTOCOCCAL GLOMERULONEPHRITIS IN CHILDREN

doi:10.1136/archdischild-2012-302724.1205

AY Naushabayeva, BA Abuezov, G Chingayeva, A Narbevok, K Kabulbayev, A Kurgibikov. Nephrology, The Kazakh National Medical University, Almaty; Pediatrics and Neonatology, Karaganda State Medical University, Karaganda; Endocrinology, The Kazakh National Medical University, Almaty, Kazakhstan

Background and Aims Nephritis syndrome (NiS) is of significant concern in Pediatric Nephrology with high progression rate. Aim of our study was to establish the pathohistological pattern, and assessment of mofetil mycophenolate efficacy (MMF) in comparison with cyclophosphamide (CYC) in children with NiS.

Methods Study was conducted in 27 children (16 boys) with chronic NiS. Kidney biopsy was performed in all patients under US-guidance using biopsy gun. Pathohistological investigation of renal biopsy included: light, immunofuorescent and electron microscopy.

Results Most frequent pathohistological variant was IgA-nephropathy (IgA-NP) (74.1%, p < 0.001). In 14.8% patients NiS was associated with hereditary nephritis. Membranoproliferative glomerulonephritis (GN) (3.7%), and extracapillary GN (3.7%) were observed rarely. To induce the remission we used IV methylprednisolone for 3–6 days, oral prednisolone (Pred) 60 mg/m²/day, MMF 1 g/m²/day for 3–4 months. Remission was established when proteinuria was decreased to 0.5 g/day. Maintenance therapy was administered for one year or longer. Controls were administered with IV (5–6 pulses) or oral (for 2 months) CYC, Pred 60 mg/m²/day for 1.5–2 months with following alternating schedule. All patients have received ACE inhibitors. Proteinuria was significantly (p < 0.05) lower in main group (0.1 g/day) in comparison with controls (0.9 g/day), and GFR increasing was more prominent in main group (from 64.3 to 98.7 ml/min/1.73m²), than in controls (from 68.9 to 59.1 ml/min/1.73m²) (p < 0.05).

Conclusions Thus, chronic nephritic syndrome in children was mostly associated with IgA-nephropathy. Combination treatment with mycophenolate mofetil + steroids and ACE inhibitors is more effective and safe than cyclophosphamide treatment.

ASSOCIATION BETWEEN DIFFERENT ACUTE KIDNEY INJURY (AKI) DEFINITIONS AND MORTALITY IN VERY LOW BIRTH WEIGHT (VLBW) INFANTS

doi:10.1136/archdischild-2012-302724.1206

MT Smelli, G Paterlini, P Grillo, P Tagliabue. Fondazione MBMB-Ospedale S.Gerardo, Monza. Fondazione IRCCS Ca’ Granda – Ospedale Maggiore Policlinico, Milan, Italy

Background AKI has been associated with increased mortality rate among VLBW infants. The best creatinine-based definition for AKI is still unclear. Our aim was to correlate mortality and different AKI-definitions.

Methods From January 1st 2005 to December 31st 2011 all VLBW infants born at S. Gerardo Hospital were recruited whenever ≥2 consecutive p-creatinine determined within 48 hours between 3 and 15 days of life were available.

AKI was defined as single creatinine ≥1.5 mg/dl (AKI-1), increase of ≥20.5 mg/dl within 48h (AKI-2) or increase of ≥50% within 48h (AKI-3).

The statistical concordance between the definitions was evaluated using the Cohen’s Kappa coefficient and their association with mortality using uni- and multivariable logistic regression. AKI-definitions were adjusted for each other and for GA, BW and Apgar score.

Results Among 263 VLBW infants, 28 (10.6%), 40 (15.2%) and 26 (9.9%) met the definition for AKI-1, AKI-2 and AKI-3 respectively. Low agreement was shown between AKI-1/AKI-2 (Kappa 0.43, 95%CI:0.27–0.59) and AKI-1/AKI-3 (Kappa 0.52, 95%CI:0.14–0.51). Substantial agreement was observed for AKI-2/AKI-3 (Kappa 0.69, 95%CI:0.56–0.82).

68/263 patients died (28.8%), with AKI-1 45.1%, AKI-2 52.5% and AKI-3 26.9% respectively.

AKI patients run higher risk of death than the others (Crude OR 15.6 [P<0.001], 6.7 [P<0.001] and 3.8 [P<0.007] for AKI-1, AKI-2 and AKI-3).

Using multivariable model, AKI-1 and AKI-2 remained associated with higher mortality (OR 4.25 [P=0.008] and OR 3.70 [P=0.041]).

Conclusions Different AKI-definitions lead to substantially different patients classifications. Even minimal increment of creatinine are associated with augmented risk of death among VLBW infants.

TREATMENT AND DIAGNOSIS OF THE NEPHRITIC SYNDROME IN CHILDREN

doi:10.1136/archdischild-2012-302724.1207
