Background and aims Severe childhood pneumonia and severe acute malnutrition (SAM) require hospitalized management but inadequate pediatric beds limits hospital-care in Bangladesh. As two prospective observational studies showed that day-care facility-based management of severe pneumonia and SAM were successful as alternatives to hospitalization, a RCT was conducted.

Methods A randomized hospital (ICHSH) versus day-care (The Radda Clinic equipped with oxygen, suction, pulse oximeter, nebulizer, glucometer) comparative study was carried out to evaluate the safety and effectiveness of day-care model. Children aged 2–59 months having severe pneumonia with SAM were randomized to day-care or hospital-care. Parents brought children at 08:00 at day-care clinic and back home at 17:00 daily after receiving antibiotics, both day-care and hospital management continued daily until improvement and discharged.

Results In total, 340 children were randomized to either day-care or hospital-care management. Successful management was possible in 136/170 [80% (95% CI 73.4–85.3%)] day-care children and 144/170 [84.7% (95% CI 78.5–89.3%)] hospital-care children. Of remaining 34 day-care children, 29 [17.1% (95% CI 12.1–23.4%)] were referred to hospital and 5 [2.9% (95% CI 1.3–6.7%)] discontinued treatment. Of remaining 26 hospital-care children, 18 [10.6% (95% CI 6.8–16.1%)] were referred to specialized hospitals and 6 [3.5% (95% CI 1.6–7.5%)] discontinued treatment.

Conclusion Children with severe pneumonia with SAM could be treated safely and effectively on a day-care basis at established day-care clinics, similar to hospital management, if required logistic support is available.

Background and aims Smoking in pregnancy significantly increases the risk of preterm birth and fetal growth restriction. Pregnant women are encouraged to quit smoking. Smoking in general is discouraged by antismoking laws. In the present study, we describe trends in smoking in pregnancy in the Netherlands for 2001–2010.

Results Out of a total number of 28,720 questionnaires, 16,358 (57%) were returned. Between 2001 and 2010, prevalence of smoking in pregnancy dropped by half; from 13.0% in 2001 to 6.3% in 2010 ($P_{\text{trend}} < 0.001$). The odds of being a smoker was 6.3 (95% CI 5.3–7.4) for mothers with a low education level, and 3.0 (95% CI 2.5–3.5) for mothers with a medium education level, as compared to mothers with high education level. Independently of their educational level, mothers smoked on average five cigarettes per day while pregnant.

We observed a sharp decrease in prevalence of smoking in pregnancy from 2003 to 2005 among women with a medium or a high education level. An almost continuous, downward trend was seen among mothers with a low level education. The 2003–2005 decrease coincided with the implementation of antismoking laws in the Netherlands.

Conclusions Between 2001 and 2010, prevalence of smoking in pregnancy dropped by half. But still, in 2010, 6.3% of Dutch pregnant women were smokers, exposing about 11,000 unborn children per year to significantly increased health risks.
Results  Hyperoxia induced severe lung damage as evidenced by cell infiltration, edema and fibrosis which were reduced significantly by CDP-choline treatment. Radial alveolar count and lamellar body protein expression were significantly recovered, while number of TUNEL-positive cells and active Caspase-3 expression were decreased by CDP-choline administration. Tissue proinflammatory cytokine (IL-1β, IL-6 and TNF-α) levels as well as tissue MDA content and MPO activities were reduced, whereas GSH-Px and SOD activities were preserved in hyperoxia+CDP-choline group.

Conclusions  Our data show for the first time that parenteral CDP-choline administration prevents hyperoxic lung injury in a neonatal rat model of BPD. It may therefore be suggested that CDP-choline can be used as an effective therapeutic agent for prevention of BPD in case it exhibits similar effects in humans.

THE PRETERM PHENOTYPE - A COGNITIVE MODEL EXPLAINS THE PROSPECTIVE RELATIONSHIP BETWEEN PREMATURENESS AND MATHEMATICAL PERFORMANCE DEFICITS

Background and aims  The human brain is highly susceptible to the consequences of preterm birth. Cognitive tasks vary in complexity and resource requirements, thus performance on tasks with different demands may provide information on specific cognitive differences in children related to the degree of prematurity. Mathematical performance requires simultaneous processing of information which is particularly compromised in preterm children. Our aim was to investigate the relationships between task complexity and incremental performance deficits across the full spectrum of gestational age (GA).

Methods  1,513 children ranging from 27 to 43 weeks GA were studied from birth to 8; 5 years as part of a prospective geographically defined longitudinal investigation of neonatal at-risk children studied from birth to 8; 5 years as part of a prospective geographical and resource requirements, thus performance on tasks with different demands may provide information on specific cognitive differences in children related to the degree of prematurity. Mathematical performance requires simultaneous processing of information which is particularly compromised in preterm children. Our aim was to investigate the relationships between task complexity and incremental performance deficits across the full spectrum of gestational age (GA).

Results  Results were twofold:

1. Preterm children showed incremental performance deficits with increasing task complexity.
2. There was a curvilinear relationship between GA and task performance with a point of change around 32 weeks of GA.

In general, every last week of gestation increased the adverse impact on performance. However, this relationship was strongest among tasks which required the highest cognitive workload.

Conclusions  With increasing cognitive workload preterm children fall behind in test scores. This suggests that brain organisation or damage limits cognitive resources. The relationship between GA and task performance is curvilinear. Our approach may offer a theoretical foundation to scrutinize the cognitive characteristics of the preterm phenotype.

EXECUTIVE FUNCTION AND IT’S IMPACT ON MATHEMATICAL UNDERACHIEVEMENT AND ATTENTION PROBLEMS IN VERY PRETERM CHILDREN

Background and aims  Despite the dramatically increased survival rates for very preterm (gestational age ≤ 30 weeks) infants, these children’s developmental outcomes remain of significant concern. A majority of non-disabled very preterm children with IQs in the average range have substantial academic and behavior problems, of which deficits in mathematics and symptoms of inattention are the most pronounced. Executive function may be an important mechanism underlying these problems, an issue only scarcely examined and aim of this study.

Methods  Two-hundred non-disabled very preterm (mean age = 8.2±2.5) and 230 term children (mean age = 8.3±2.3), all born between 1996 and 2004, were assessed with measures of mathematics/arithmetic (Dutch Pupil Monitoring System), and executive function in preschool and in primary school. Parents and teachers reported on attention problems using the Achenbach behavior questionnaires and the Disruptive Behavior Disorders Rating scales.

Results  Very preterm children had significantly more mathematical and attention problems than term children (SMD’s > 0.46). IQ significantly predicted mathematical problems (βs > 0.15, Ps < 0.04). Executive functioning, in particular spatial span and inhibitory control, was over and above IQ, significantly predictive for mathematic problems (βs = 0.11, P=0.005) and attention problems (βs > 0.17, Ps < 0.001) in primary school. Associations were stronger for very preterm than for term children.

Conclusions  Very preterm birth is associated with medium-sized deficits in mathematics and attention problems. Impaired executive function and IQ scores are important predictors for these adverse outcomes.

PHARMACOKINETICS AND CLINICAL EFFICACY OF PHENOBARBITAL IN ASPHYXIATED NEWBORNS TREATED WITH THERAPEUTIC HYPOTHERMIA

Background and aims  Therapeutic moderate hypothermia for neuroprotection in the asphyxiated newborn can influence pharmacokinetics and pharmacodynamics. If seizures occur, phenobarbital is the anticonvulsant of first choice. The aim of this study was to evaluate the effect of therapeutic hypothermia on phenobarbital pharmacokinetics and to evaluate the clinical efficacy of phenobarbital under hypothermia.

Methods  Data were obtained from a prospective study in two Dutch level III NICUs (SHIVER-study). Term born newborns with criteria of perinatal asphyxia and encephalopathy were included. Therapeutic hypothermia (33.5°C) was started within 6 hours after birth and was maintained for 72 hours. Pharmacokinetic modelling was performed using NONMEM.

Results  In total, 31 term-born newborns were included of which 87 plasma samples were obtained (69 samples during the hypothermic phase). Based on a one-compartmental model with allometric relationships, clearance and distribution volume were estimated at 17.2 mL/h/3.5kg and 3450 mL/3.5kg respectively. No relationship between hypothermia and pharmacokinetic parameters was identified. Overall, 66% of all neonates demonstrated sufficient seizure control with phenobarbital monotherapy, even though 69% of all measured concentrations were below 20 mg/L. In 88% of neonates...
