The objective: Evaluation of fetal and neonatal immediate impact of pregnancy hypertensive disease, and a comparison between the severity of gestational hypertensive disease and neonatal outcome.

Materials and Methods This work was based on the analysis of the neonatology registries of the maternity service in Rabat’s university hospital during 2010. We selected the newborns from mothers with gestational hypertension, and we clarified the evolutionary stage of this disease. A standardized form of farm has been established for this purpose.

Results 560 newborns met the analysis criteria, that is, 3.69% of all newborns during this period. The average age of the parturients was 28±12 years. Delivery has been advocated by Cesarean in 53.2% of cases, perinatal asphyxia was associated in 12.8% of cases. The prematurity rate was 16.8%. The hypertrophy was observed in 44% and macrosomia in 3% of cases. Fetal mortality was observed in 10.7% of cases.

The pēclampsie represents 28.5% of cases, and retroplacental hematoma which is the most frequent maternal complication was 9.1%. Mortality and neonatal morbidity changes depending on maternal complications. Mortality and neonatal morbidity vary significantly according to maternal complications. In this study, the retroplacental hematoma, the helpp syndrome and eclampsia are responsible for a high rate of fetal mortality (27.5%), neonatal mortality (12%) and perinatal asphyxia (39.6%) compared to preeclampsia and uncomplicated gestational hypertension.

Conclusion There is a clear correlation between the stage of the gestational hypertension evolution and the newborn’s prognosis. The latter can be improved by a correct maternal prenatal monitoring.

A1274 A COMPARATIVE STUDY OF KLIMEK AND BALLARD METHODS IN DETERMINING NEONATAL MATURITY IN IRAN doi:10.1136/archdischild-2012-302724.1274

R Saeedi, S Rahmani, S Loeo, Mashhad University of Medical Sciences, Mashhad, Iran

Background and purpose: Severe prematurity, as the most important factor in premature neonatal mortality, is of paramount importance and accounts for 60–80% of neonatal mortality without abnormalities. Therefore, by defining the exact time of fetal maturity, complications and side effects could be predicted and best decisions could be made. Since the present methods are complicated, time-consuming and stressful for the neonates, researchers decided to compare the simple Klimek method with the New Ballard method.

Methods and materials: This study is a descriptive cross-sectional research. Qualified neonates in a single group were examined for maturity by both Klimek and New Ballard methods. Neonate was examined by the first co-researcher with New Ballard method, and immediately examined by the second co-researcher with Klimek method. The second neonate was examined by the first co-researcher with Klimek method and then immediately by the second co-researcher with Ballard method. All 229 neonates were examined in this way. The examinations were done in the first 6–12 hours after birth. Analysis of data was conducted in SPSS, using Mann Whitney U and Kappa Coefficient.

Results In 74.6% (171 cases) the same gestational age was obtained by both methods (p=0.664). Also, determination of gestational age by Klimek method and LMP was not statistically different; and 75.9% (174 cases) the same gestational age was obtained by both methods (p=0.943). In 51.5% (118 cases), both methods detected mature neonates (K=0.806).

Conclusion The simple Klimek Method is completely compatible with the New Ballard and LMP methods in determining neonatal maturity.

The major and minor neurodevelopmental morbidities among premature infants become an important issue because of the increase in the number of surviving premature newborns, especially in the smaller gestational age group.

The aim of this study was to examine the neuromotor outcome of the premature newborns at 4–6 years of age with very low birth weight and to investigate the risk factors associated with this outcome.

The present study was conducted in 70 very low birth weight children born during April 2004 and June 2007. The neuromotor status of 68 children was evaluated according to Touwen. The hospital records of the children were scanned for various risk factors.

Three cases were already diagnosed and followed as CP. The remaining 65 children did not meet the criteria for CP. According to Touwen examination 28 (%41.2) children were considered as normal, 35 (%51.5) had simple minor neurological dysfunction, 2 (%2.9) had complex minor neurological dysfunction.

35 children with minor neurological dysfunction and 28 children with normal neuromotor status were compared for some risk factors. The children with minor neurological dysfunction had significantly lower Apgar score, their hospitalization period was longer and the diagnosis rate of clinical (%73.5; %25) and culture proven sepsis (%47.1; %10.7) was higher in this group.

Sepsis was significantly associated with adverse neurological outcome. The prevention of neonatal sepsis in NICU’s will increase the chance for healthy neurological development.
Neonatal mortality and morbidity in extremely preterm infants (<28 weeks of gestation) have been extensively studied, but the risk added by intrauterine growth restriction remains controversial.

**Background** Neonatal mortality and morbidity in extremely preterm infants (<28 weeks of gestation, SGA) are associated with increased risk of intrauterine growth restriction. SGA is defined as birth weight < 10th percentile for gestational age. The Risk of mortality and morbidity in the SGA group is evaluated by comparing outcomes for SGA against a non-SGA reference group.

**Methods** The study included 9,888 singleton extremely preterm infants whose live birth was recorded at the Neonatal Research Network in Japan during 2003–2010. SGA was defined as birth weight at least 2SD below the mean for gestational age. The Risk of mortality and morbidity in the SGA group was evaluated by comparing outcomes for SGA against a non-SGA reference group.

**Results** Of the study subjects, 1,215 (12.3%) were SGA. Controlling for gestational age, sex, parity and multiple gestation, SGA infants showed a higher mortality rate during NICU stay compared with reference group infants (odds ratio [OR]: 4.23, p<0.0001). Severe neonatal asphyxia (OR: 1.89, p<0.0001), RDS (OR: 1.33, p<0.0001), chronic lung disease at 36 weeks’ postmenstrual age (OR: 2.23, p<0.0001), sepsis (OR: 1.95, p<0.0001), necrotizing enterocolitis (OR: 1.93, p<0.0001), focal intestinal perforation (OR: 1.46, p=0.011) and congenital anomalies (OR: 2.66, p<0.0001) were significantly associated with SGA status.

**Conclusion** Extremely preterm SGA infants are associated with increased risk of neonatal mortality and morbidity. These results are important for obstetric counseling and decision making and treatment of extremely preterm infants.

**1278** OUTCOME FOLLOWING FETAL PLEUROAMNIOTIC SHUNTING IN 114 LARGE HYDROTHORACES

doi:10.1136/archdischild-2012-302724.1278

**Introduction** Untreated, fetal hydrothorax is associated with significant morbidity and a mortality rate of approximately 80–90%.

**Population** 114 fetuses with isolated large pleural effusions underwent pleuroamniotic shunting at our perinatal centre. All had an extensive antenatal work-up including: detailed anatomy, echocardiogram, karyotype, infectious testing for CMV, Toxoplasmosis and Parvovirus. 84 were bilateral, 72 (65%) were hydropic and 41 (36%) diagnosed with hydrothorax. Of these 114 fetuses, 15 (12.3%) intrauterine deaths and 73 (64.7%) survivors. Additional abnormalities including genetic, metabolic and neurological syndromes were identified antenatally in 8 cases and postnatally in 9. Of 99 liveborn babies, 76 (77%) delivered at our perinatal centre. Postnatally, 46 required ventilation, 38 (50%) required chest tubes, of whom 19 (26%) died. Of 73 survivors, 2 (3%) were lost to follow-up, 4 (5.5%) were < 4 months of age, 10 (14%) showed evidence of significant developmental delay, including 3 with Trisomy 21, and 1 had mild developmental delay. Fifty five (75%) are developing normally. Fetal therapy significantly improves perinatal outcome, although mortality remains high. On long term follow up, approximately 75% of survivors are developmentally normal.

**Background and Aims** Therapeutic hypothermia (TH) is now a standard of care for neonatal encephalopathy (NE). We have previously shown that referrals for TH in the London region have steadily increased since the publication of TOBY study but documentation of cooling criteria was poor (43%) before transfer to cooling centres. In this study we audit referrals for TH following introduction of a structured proforma and the early outcomes of these babies.

**Methodology** Prospective audit of referrals for TH to a regional neonatal transfer service over a six-month period (May–October 2011). Audit registered with the Clinical Effectiveness unit of the NHS Trust. Following transfer, cooling centre was contacted to find out early outcomes: if infants received TH for 72 hours and outcome at 7 days.

**Results** 43 referrals for TH were received. The median Gestation was 40 (35–42) weeks. Birth-weight 5.42 (2.04–4.84) Kg. Of these 38 transfers were performed. Completed proforma was available in 21 cases. TOBY criteria A were recorded in 100% of cases and TOBY criteria B in 88%. 8 (21%) infants did not receive TH for 72 hours as assessed to not benefit from TH of which 3 died within 72 hours. At 7 days of age 5 were discharged home and remaining 30 were inpatients.

**Conclusions** Our audit shows that introduction of a structured proforma can improve documentation of cooling criteria and neurological examination. We recommend that any referral for TH is carefully selected to avoid unnecessary transfer of neonates who may not benefit from TH.

**1279** EARLY OUTCOMES FOLLOWING REFERRALS FOR THERAPEUTIC HYPOTHERMIA - A REGIONAL NEONATAL TRANSFER SERVICE PERSPECTIVE

doi:10.1136/archdischild-2012-302724.1279

**Background and Aims** Neonatal Intensive Care Unit (NICU) is a noisy environment in which infants can be exposed to high noise levels. The aim of the study is to evaluate the adverse effects of noise on hearing and neurological outcomes in NICU graduates at six months of age.

**Methods** Thirty two infants that had been admitted to Gazi University Hospital NICU and 25 healthy controls, were included in the study. Noise levels were recorded continuously during hospitalization period. TEOAE, DPOAE and ABR tests were used to assess hearing. Neurological outcome was assessed with Bayley II Development Scale.

**Results** The median period of noise exposure above 45 dB was 50.1% of the entire hospitalization period. Levels exceeding 45 dB were mostly below 124 Hz. Major source of noise was traced back to the incubators. All patients passed the hearing screening tests before discharge. On the sixth month follow up, hospitalized infants had lower DPOAE SNR amplitudes (dB) at five frequencies including 1001, 1501, 3003, 4004, 6006 Hz in both ears. DPOAE fail rates at 1001 Hz and 1501 Hz were higher in hospitalized infants.
