differences lead to a different movement pattern of the affected arm. The effect of the OBPP on the level of activity and participation seems to be of no importance. The children with an OBPP do not stay behind with children of their age in physical and social activities.

Conclusions Children with a conservative treated OBPP have persisting restrictions specially on the level of body functions and structure. Despite these restrictions there is no relevant effect shown on the activity and participation level. Using the mobility tests we think there is a relation between position of the scapula and the joint mobility.

1318 SMOKING AND OTHER PRE-GESTATIONAL RISK FACTORS FOR SPONTANEOUS PRETERM BIRTH

doi:10.1136/archdischild-2012-302724.1318

Objectives To investigate pre-gestational risk factors for spontaneous preterm birth and, the role of smoking and its cumulative effects on prematurity.

Methods A case-control study analyzed all births (2,198) occurring in a tertiary maternity hospital between April 2002 and July 2004. Spontaneous preterm births of single and live newborns without malformations were selected as cases. Controls were all the term births of live and single newborns without malformations during the same period. Three outcomes were studied: all preterm births (<37 weeks), less than 35 weeks and less than 32 weeks of gestational age. Logistic regression was used to obtain the independent effect of pre-gestational risk factors.

Results Maternal age of less than 20 years, low schooling, low maternal pre-gestational body mass index and smoking showed significant, independent association with spontaneous preterm birth for the three outcomes. For all these risk factors, excepting maternal smoking, odds ratios increased with decreasing gestational age at birth and this trend was significant for low maternal age and low pre-gestational body mass index.

Conclusions The cumulative effects of smoking calls for the need to encourage smoking cessation among pregnant women, especially those who are underweight and in the older age groups, because of the increased risk of delivering premature babies.

1319 VITAMIN D LEVELS IN NEAR TERM INFANTS

doi:10.1136/archdischild-2012-302724.1319

1W Al-Harthy, 2D El-Metwaly, 3MM Abou Al-Seoud. 1Neonatal Division, Paediatric Department, Maternity and Children Hospital, Makka, Saudi Arabia; 2Paediatric, Suez Canal University (FOMSCU), Ismaillia, Egypt; 3Neonatal Division, Paediatric Department, King Fahad Armed Forces Hospital, Jeddah, Saudi Arabia

Background and Aims Based on the fact that the whole-body bone mineral content increases between 32–33 wk and 40–41 wk gestation (5.0 fold increase), near-term infants are thus at higher risk for low levels of vitamin D. Our aim was to measure 25-hydroxyvitamin D [25(OH)D] concentrations in the cord blood of near term infants born at KFAFH in Jeddah Saudi Arabia.

Methods This was a prospective study carried out from August 1st 2011 to January 31st 2012. A total of 158 near term babies with gestational ages 34 to 36+6 weeks were included. The results were classified as: Deficient (25(OH) D<37.5 nmol/L), Insufficient (25(OH) D 37.5–7.5 nmol/L) or Sufficient (25(OH) D>75 nmol/L).

Results The measured 25(OH) D levels ranged between 3–91 nmol/L with a mean of 26.9±13.9 nmol/L. The values were classified as deficient in 134 babies (88.2%) and insufficient in 16 babies (10.5%), while only two babies (1.3%) had sufficient levels of vitamin D in their cord blood. We ran correlation studies between 25(OH) D levels, birth weight (BWt), gestational age (GA) and admission to the neonatal intensive care (NICU), there was a weak correlation between 25 (OH) D levels and birth weight (p value of 0.172) but no correlation was found with GA or NICU admission.

Conclusion We observed a high prevalence of significant hypovitaminosis D among near term infants and a weak correlation with lower birth weight, the magnitude of which warrants identification and intervention.
