Background Preterm infants at term equivalent age are smaller than full term infants with a higher fat mass. The aim of this study was to determine if alterations in adiposity are already evident at 32–36 weeks corrected age (CA).

Methods Preterm babies (n=21) born before 32 weeks gestation were studied between 32 and 36 weeks CA using the PEAPOD Infant Body Composition System to assess % body fat. The data were compared with a second group of babies (n=17) born at 32–36 weeks gestation.

Results Mean % body fat at 32–36w CA in infants born < 32w was 14.1±2.5 (mean ± SD) and this was significantly higher than % body fat in infants born at 32–36 weeks (7.9±4.5, P<0.01). Mean % body fat at 32–36 weeks in infants born < 32w was also significantly higher than % fat at birth in infants born at term (10.1±4.1, P<0.05). % body fat in infants born < 32w was positively correlated (R=0.59, P<0.05) with post-natal age at measurement suggesting that longer periods of ex utero nutrition result in greater increases on % body fat. % body fat in infants born < 32w was also positively correlated with weight at the time of measurement (R=0.56, P<0.01) and there was a tendency for those babies who had gained weight most rapidly since birth to have higher % fat.

Conclusion % body fat in infants born < 32 weeks is elevated by 32–36 weeks CA.

Abstract 1348 Figure 1 Study Groups

Formation of PI reached 25% at 4h, and did not appear to have plateaued.

Conclusions Formation of PI is rapid during intensive phototherapy. However, increasing irradiance or changing the character of the light source did not significantly improve the rate or level of PI formation.

Background and Aims Infants with maternal vitamin D deficiency are at increased risk of low vitamin D levels. Cholecalciferol is the usual treatment for such infants. We wanted to see whether routine vitamin supplementation with Abidec alone was enough to normalize vitamin D levels in such infants.

Methods All infants with maternal vitamin D deficiency, after August 2011 were given 0.6ml Abidec which provides 400IU of vitamin D2. Vitamin D levels were done at birth and infants with borderline (10–20ng/dl) or deficient (<10ng/dl) vitamin D levels had repeat test at follow-up. Records of all such infants, from August to November 2011 were reviewed. The results were also compared to the period when cholecalciferol was used.

Results Total 64 patients were identified. Initial vitamin D results were obtained for 60 infants of which 16 infants were deficient (range 3.1 to 9.1 ng/dl), 20 had borderline (range 10.3–19.8 ng/dl), 10 had suboptimal (range 20.6–29.7ng/dl) and 14 infants had normal vitamin D levels. Post treatment levels were available for 17 out of 36 infants with low or borderline levels. Of the 5 infants with initially deficient levels, 3 had normal, 1 had suboptimal and 1 had borderline vitamin D post treatment levels. 8 of the 12 infants with borderline vitamin D levels had normalized and 4 had suboptimal vitamin D levels post treatment.

These results were comparable to the period when cholecalciferol was used.
