Objective To investigate cognitive function in obese Egyptian adolescents.

Methods A stratified-cluster proportionate random sampling was used to select a representative sample of 4899 pupils in preparatory school aged 12–15 year. Overweight was defined as BMI ≥85th but <95th percentile, while obesity as ≥95th BMI percentile, using Egyptian percentile. Wechsler Intelligence Scale and Executive Function test were used to assess cognitive function.

Results The prevalence of overweight was 14.9% and obesity was 6.6%. The children's mean full scale IQ was 89.54. Wechsler Intelligence Scale revealed significant differences in performance intelligence quotient (PIQ) scores between overweight and obese children. Parental education was significantly related to total intelligence quotient (TIQ) (p = 0.03). Executive function was significantly impaired in obese adolescents. Executive function was significantly lower in obese than overweight adolescents. After adjustment for age and parental education level female obese adolescents had lower cognitive function than male obese adolescents. BMI and waist circumference were the best predictor of impaired cognitive function in obese and overweight adolescents.

Conclusion Overweight and obesity were associated with cognitive dysfunction in adolescents.

Aim of the work To determine the extent and severity of the aforementioned obesity-related atherosclerotic risk factors among school aged children and adolescents.

Subjects and methods The sample has included 98 obese (non-syndromic) and 36 non obese control subjects aged 6–16 years. A questionnaire was filled to evaluate the daily and weekly PA calculated in hours, anthropometry was done and blood pressure was measured, together with assessment of serum lipid profile and levels of fasting blood sugar, ALT, UA, E-selectin and hs CRP.

Results 55% of obese group have shown 4 or 5 atherosclerotic RFs. One or more features of abnormal lipid profile were found in 94% of obese group with 73% showing high cholesterol level. ALT and UA were significantly higher in the obese group, similarly E-selectin that was elevated in 71% of obese and hs CRP were significantly higher among obese. FBS did not show similar significant elevations. Positive correlations were found between cholesterol, E-selectin and hs CRP with BMI and waist/hip ratio.

Conclusion Most of obese children and adolescents do suffer from some risk factors that can lead to an earlier and greater risk for developing atherosclerosis.

Introduction Childhood is more often nowadays confronting with a different pathology, specific to adulthood like obesity, diabetes mellitus, essential hypertension and hypercholesterolemia. The prevalence of these diseases is rising and cardiovascular risk factors are present even in children and the key is represented by the process of atherosclerosis.

Objective The aim of our study is to determine the presence of cardiovascular risk factors in childhood and if there is any evidence of atherosclerosis effects on the vessels.

Material and method The study had included 80 children, boys and girls, aged between 10 and 18 years. All of the children had obesity. The protocol of investigations had consisted in: blood pressure measurement (BP), body mass index calculation (BMI), blood levels of glucose, oral test of glucose tolerance, cholesterol, triglycerides, low density lipoproteins, high density lipoproteins, echocardiography and measurement of the mass of the left ventricle, Doppler ecography of the common carotid artery and measurement of the intima-media thickness (IMTc) as a evidence of the atherosclerotic process.

Results We had found a stong and positive correlation between IMTc and BMI, systolic BP, the level of total cholesterol, triglycerides and a negative correlation with the level of high density lipoproteins. All the subjects had had impairment of the oral test of glucose tolerance.

Conclusions The rising incidence of obesity in children is a reality. It is strongly connected with the atherosclerosis and its consequences, like early structural changes of artery, even in childhood, and therefore prevention should be a priority.

Introduction Atherosclerosis is among the important long term complications and leading causes of death among obese children and adolescents. Its risk factors (RFs) include mainly: high body mass index (BMI), central obesity, smoking, lack of physical activity (PA), hypertension, hyperglycemia, elevated uric acid (UA), alanine aminotransferase (ALT), inflammation, adhesion molecules (as E-selectin) and highly sensitive (hs) CRP.

Objective To examine the extent and severity of the aforementioned obesity-related atherosclerotic risk factors among school aged children and adolescents.

Subjects and methods The sample has included 98 obese (non-syndromic) and 36 non obese control subjects aged 6–16 years. A questionnaire was filled to evaluate the daily and weekly PA calculated in hours, anthropometry was done and blood pressure was measured, together with assessment of serum lipid profile and levels of fasting blood sugar, ALT, UA, E-selectin and hs CRP.

Results 55% of obese group have shown 4 or 5 atherosclerotic RFs. One or more features of abnormal lipid profile were found in 94% of obese group with 73% showing high cholesterol level. ALT and UA were significantly higher in the obese group, similarly E-selectin that was elevated in 71% of obese and hs CRP were significantly higher among obese. FBS did not show similar significant elevations. Positive correlations were found between cholesterol, E-selectin and hs CRP with BMI and waist/hip ratio.

Atherosclerosis Risk Factors in Obese Children and Adolescents

S Atef, T Adham. Ain Shams University, Cairo, Egypt

Introduction Atherosclerosis is among the important long term complications and leading causes of death among obese children and adolescents. Its risk factors (RFs) include mainly: high body mass index (BMI), central obesity, smoking, lack of physical activity (PA), hypertension, hyperglycemia, elevated uric acid (UA), alanine aminotransferase (ALT), inflammation, adhesion molecules (as E-selectin) and highly sensitive (hs) CRP.

Objective To investigate cognitive function in obese Egyptian adolescents.

Vitamin D Deficiency and Secondary Hyperparathyroidism in Obese Children

R Ghergherehchi, N Hazhir, A Tabrizi. Pediatric Endocrinology, Tabriz University of Medical Sciences; Tabriz Children Hospital University of Medical Sciences, Tabriz, Iran

Obesity subjects individuals into metabolic and endocrine disorders. Thus obesity may increase the risk of vitamin D deficiency. This text aims at studying the prevalence of vitamin D deficiency and secondary hyperparathyroidism in obese children. In a non-randomized
case control study on 52 obese children (body mass index (BMI)>95th percentile) aged 4 to 16 years undertaken at the outpatient endocrine clinic of the Children Hospital at Tabriz University between 2009–2011. This study was conducted to compare the prevalence of vitamin D deficiency and secondary hyperparathyroidism in obese children compared with 57 non obese (BMI< 85th percentile). 109 children including 52 (50.5%) boys and 57 (49.5%) girls were studied. Most of case (76.9%) and control (42.1%) groups were defined to all patients. The results were processed using ± mean ± SD age 14.2 ± 3, group2 MS 16/13), = 0.04). Insulin(Ins); total cholesterol(TC); triglycerides(TG); high-density(HDLc), low-density(LDLc) lipoprotein cholesterol; atherogenic coefficient(AC); OGTT with HOMAIR index were defined to all patients. The results were processed using the Statistica 6.1.

Results BMI boys group1 28.1 ± 5.4 kg/m2, group2 33.8 ± 4.4 (p=0.3); group1 girls 31.5±5.6, group2 36±5.5 (p=0.6). The average levels of TC were in normal limits, gender and intergroup differences weren’t noted (p=0.1). TG boys and girls with MS were 1.73±0.98 and 2.02±0.6 (0.45–1.7 mmol/l), the reliable difference weren’t noted (p=0.8 and p=0.3 respectively). HDLc was norm in all groups regardless of gender (p=0.2). LDLc was upgraded in girls group2 3.42±0.79 (< 3.3 mmol/l) (p=0.4). AC in boys and girls group2 was 3.31±1.6 and 3.81±0.8 (2–5) (p=0.1). Basal and postprandial plasma glucose levels by conducting OGTT didn’t exceed normal limits in group1 and group2 regardless of gender (p=0.08). Ins boys group1 24.2±18 mU/ml (2.1–22), group2 40.1±23.2 (p=0.1); girls group1 20.8±14, group2 37.8±16.1 (p=0.6). HOMAIR boys group1 5.16±3 (< 2.77), group2 10.87±5.9 (p=0.1); girls group1 4.15±3, group2 8.5±4 (p=0.8).

Conclusions Dyslipidemia was typical to group with MS. Insulin resistance with maintaining the basal and postrandial normoglycemia was noted by conducting OGTT in all patients regardless of gender.

1436 MATERNAL WEIGHT GAIN DURING PREGNANCY AND NEONATAL BIRTH WEIGHT: MOROCCAN DATA

doi:10.1136/archdischild-2012-302724.1436

1A Barkat, 1L Machhoury. équipe de Recherche en Santé et Nutrition du Couple Mère Enfant, Faculté de Médecine et de Pharmacie de Rabat, Université Souissi; 2Faculté de Médecine et de Pharmacie de Rabat; Université Souissi, Rabat, Morocco

Objective The objective of this study was to investigate the influence of maternal weight gain on birth weight of a population of newborns.

Patients and Methods Study including all patients who delivered in the service of the Maternity Hospital Provincial BENSILMANE between 1 October 2010 and October 1, 2011. Three groups of patients were formed according to weight gain: less than 8kg, between 8 and 16kg and over 16kg normal. The epidemiological characteristics, obstetric complications and neonatal outcomes were analyzed. The survey is conducted on the basis of a questionnaire, for parturients and obstetric records analysis.

Results The mean birth weight was higher in the group “weight gain ≥ 16 kg” (3782.9±595 g p<0.05) and the rate of newborns weighing more than 3800g (45.5%, p<0.05), unlike those weighing less than 2600g (hydropotrophy) whose percentage was higher in the group “weight gain < 8 kg” (6.2% p<0.05), weight gain greater than 16 kg represented a risk factor for dystocia (34.7%).

Conclusion An excessive weight gain during pregnancy has deleterious effects on neonatal trophicity. It promotes macrosomia. These data point out the interest to follow the recommendations of weight gain during pregnancy.

1437 MARKERS OF THE METABOLIC SYNDROME AND PHYSICAL ACTIVITY IN TEENAGE CHILDREN BORN PRETERM

doi:10.1136/archdischild-2012-302724.1437

1R Tinnion, 1K Hollingsworth, 1L Basterfield, 1M Tremell, 1T Cheetham, 1N Embleton. 2Institute of Health and Society; 3Newcastle Magnetic Resonance Centre; Institute of Cellular Medicine, Newcastle University; 4Newcastle upon Tyne Hospitals NHS Foundation Trust; 5Newcastle University, Newcastle upon Tyne, UK

Background and Aims The worldwide increase in the Metabolic Syndrome is associated with adverse health outcomes and significant healthcare costs. Early life exposures are key factors in determining later health. Children born preterm appear to be at higher risk of developing insulin resistance. We aimed to determine the prevalence of novel metabolic biomarkers in a cohort of teenage children who were born preterm (≤34 weeks gestation) and correlate these with physical activity.

Methods We studied 24 children using standard techniques including auxology, body composition (BODPOD™), insulin resistance...
