Results Duration of hospitalization of the I group was 6.15±0.24 days, the II group - 5.29±0.22 days, the III group - 4.26±0.25 days (P<0.001). In children of the I group 73.7% were recovered, in children of the II group - 78.2%, and in children of the III group - 85.7% of children.

Conclusions The minimin invasive method of endoscopic surgery in the proper modification made possible the more rapid recovery from the inflammatory process in the patients with recurrent and chronic sinusitis.

1583 CLINICAL AND ULTRASOUND EXAMINATION AFTER UNILATERAL ORCHIEPOXY

doi:10.1136/archdischild-2012-302724.1583

J de Lafolie, S Turial, R Freudenberger, V Engel, F Schier. General Pediatrics and Neonatology, University of Giessen, Giessen; Department of Pediatric Surgery, University of Mainz, Mainz, Germany

Aim To compare testes volume and ultrasound texture post unilateral orchiectomy with the other side.

Methods Clinical re-examination and ultrasound measurement of testicle volume and echostucture were performed in 99 children after unilateral orchiectomy, performed between 2003 and 2007.

Results Intraperative, 30 tests were described as hypoplastic, further 5 patients displayed pathologic funicular structures.

On follow-up clinical exam, 45 patients displayed a small or atrophic testis on the side of surgery. In 10 patients, the testis was described as bigger on the side of surgery.

On ultrasound, 65 patients had similar pictures on the side of surgery compared to the other side. In the group <2 years, volume was measured as 0.2ml±0.1ml vs 0.4ml±0.2ml contralaterally (n=10). In the age group 3 to 5 years volume was measured 0.4ml±0.2ml vs 0.6ml±0.3ml (n=41), in the group 6–10 years 0.4ml±0.2ml vs 0.5ml±0.3ml (n=28) and in 11 to 17 years-old volume was 3.1±2.7ml vs 3.9±3.8ml (n=11).

Correlation of age at surgery and postsurgery volume difference between testes was r=0.6 (Pearson). In an univariate variance analysis a mild influence was found by age at surgery, inguinal hernia or re-operation.

Conclusion After orchiectomy a hypotrophic testis on the side of surgery was found in an unexpectedly high proportion. Ultrasound added valuable data (volume, texture) to the clinical follow-up examination, especially when compared to the contralateral side.

1584 APPLICABILITY OF SIGMOID COLON GRAFT FOR VAGINAL REPLACEMENT (COLOVAGINOPLASTY) AT YOUNG AGE

doi:10.1136/archdischild-2012-302724.1584

HA Al Abessy, Obstetric Gynecology, Al Azher University, Cairo, Egypt

Objective To evaluate the applicability, feasibility, complications, short and long term results of vaginoplasty by using sigmoid colon graft with the use of stapler for resuming colonic continuity in children with absent vagina.

Patients and Methods The records of 17 patients, 12 of them had Congential Adrenal Hyperplasia (CAH), 3 had Androgen Insensitiviy Syndrome (AIS) and 2 had vaginal atresia underwent sigmoid colon graft vaginal reconstruction with the aid of circular stapler during a period of 5 year from 2005 to 2010 were reviewed retrospectively.

Results A neovagina was constructed in 17 patients aged from 1 to 8 years (mean 3 years) during the study period, where sigmoid colon graft was used in all patients. Hospital stay ranged from 5 to 12 days (mean 7), operative time ranged from 60 to 120 min (mean 75). Complications occurred in 4 patients, introital stenosis in 2 patients, one of them necessitates revision of the introits and 2 cases had wound minor infection. The need for neovaginal dilation was indicated in only 8 out of 17 patients. There was no complications related to bowel anastomosis. No mortality in this group, the cosmetic results were excellent in all cases, with good patient satisfaction.

Conclusion Sigmoid colovaginoplasty appears to be applicable for remedy of vaginal atresia and at any age. It is associated with a less complication rate, the long term results is satisfactory and it seems better technique than skin flaps, especially in girls who doesn’t expect sexual activity shortly after surgery.

1585 UNILATERAL VERSUS BILATERAL SURGERY FOR INGUINAL HERNIA IN PREMATURITY BOYS: A MULTICENTER FRENCH STUDY ON 966 CASES

doi:10.1136/archdischild-2012-302724.1585

Background and Aim Bilateral surgery was formerly advocated in premature boys with unilateral inguinal hernia to avoid a metachronous contralateral hernia and the risks of recurrent anesthesia. But the recent progress in pediatric anesthesia and the demonstrated morbidity of herniotomy during the neonatal period on fertility now question this attitude. We aimed to compare the morbidity of preventive bilateral vs elective unilateral herniotomy in premature boys with unilateral hernia and to evaluate the incidence of contralateral metachronous hernia.

Methods Retrospective multicenter analysis of 966 premature boys presenting with unilateral inguinal hernia. 558 infants benefited from unilateral herniotomy and 408 from bilateral herniotomy with a median follow up of 20 months.

Results

1. The rate of contralateral metachronous hernia after unilateral surgery was 11% (10% on right vs 13% on left).

2. Morbidity on the contralateral side was higher in case of preventive bilateral surgery than in metachronous hernia (2% vs 0.2% p=0.003), especially for testicular hypotrophy (0.70% vs 0.13 %, p=0.2) and secondary cryptorchidism (1% vs 0%, p=0.05)

3. Comparison between the type anesthesias (general anesthesias versus central block) did not show significant differences depending on the type of care (unilateral or bilateral, planned or emergency).

Conclusion Systematic bilateral herniotomy is unnecessary in almost 90% of patients and has a higher morbidity than secondary surgery for metachronous hernia. These results, along with the risk of deferential damage and hypofertility reported in later adulthood, justify treating only the symptomatic side in premature boys.

1586 MINOR HYPOSPADIAS: THE "TIP OF THE ICEBERG" OF THE PARTIAL ANDROGEN INSENSITIVITY SYNDROME
