Results
Sleep duration showed a significant inverse association with weight (p<0.05) and height (p<0.005) during 7 day and weekdays. A significant relationship was found between Sleep efficiency and weight, BMI, weight for age (p<0.05) during weekdays and weekend days.

Conclusion
In the current study, we found Sleep pattern may be an important environmental factor for obesity in school age children’s. These findings are important because sleep duration is a potentially modifiable risk factor that could be important to consider in the prevention and treatment of childhood obesity.

Background and aims
Complementary and alternative medicine (CAM) use by children is predicated upon CAM-use by their parents. Of the various practitioner-based CAM therapies for children, chiropractic is the most popular. This study was undertaken to characterize the chiropractic care of children in Europe in a practitioner-based research network (PBRN).

Methods
This study was approved by the IRB of Life University (Marietta, GA, USA). European chiropractors and their patients participated in a PBRN observational study to characterize the chiropractic care of children.

Results
A convenience sample of 14 chiropractors (10 females; 4 males; average age = 59.36 years; average practice experience = 11.00 years) participated in this study and recruited a convenience sample of 64 parents whose child was receiving chiropractic care. Referrals patterns indicated 3 “often” received referrals from MDs while 15 indicated “often” referring patients to MDs.

Of the 64 children (34 females; 30 males; median age = 7.38 years; complaint duration average of 1.42 years), 47% had previously or were currently attending medical care while 53% did not. Motivation for care ran the spectrum of pediatric clinical presentations from musculoskeletal (i.e., scoliosis) to non-musculoskeletal (i.e., colic, enuresis) in addition to health promotion and disease prevention. Perceived effectiveness by 72% of parents was high as compared to the duration of the disease or to glycemic control. Therefore we recommend bone density scan for all young males with type-1 diabetes to measure BMD and try to prevent diabetic osteopenia through therapeutic intervention.

Conclusion & recommendation
Young males with type 1 diabetes exhibit significantly lower BMD values at the vertebral which may be manifested as osteopenia in the growing bone. This may not be a late complication of type 1 diabetes and seems not to be related to the duration of the disease or to glycemic control. Therefore we recommend bone density scan for all young males with type-1 diabetes to measure BMD and try to prevent diabetic osteopenia through therapeutic intervention.

Background and aims
It is believed that the medical reports submitted to the Education Department are wordy and repetitive. The aims of the audit were to create clear and concise reports for the Education as a part of the special needs assessment and to test the above hypothesis.

Methods
It is a retrospective qualitative analysis of the medical reports submitted to the Education Department by a busy Community Pediatrics department of a District General hospital. 46 reports which were submitted to the Education from January 2011 to April 2011 were analysed through a standardised audit questionnaire.

Results
Of all 46 reports, 100% had parental views expressed, 98% had no repetition, 86% had some documentation about the behaviour, in 85% the summary was clear and concise with appropriate recommendations, 82% had documentation about the hearing and 80% had documentation about the vision and developmental milestones. On the other hand only 56% had some documentation about the medications, 47% had a problem list, 28% had documentation of learning ability and 8% had documentation about strengths.

Conclusions
The hypothesis that the medical reports are wordy and repetitive is wrong however there should be clear headings for problem list, medications, vision, hearing and developmental milestones. It was found that the existing template for the medical reports was not followed. As a result of this audit, a new template for the medical reports was developed to be used by the Community Paediatricians in an attempt to provide clear and concise reports for the Education Department.
adolescents with average body mass index of 34 plus or minus 3.8 and compared with 50 age- and sex-matched controls, with a body mass index of 21.6 plus or minus 1.9. Cardiac dimensions, stroke volume, left ventricular and right ventricular systolic and diastolic functions were evaluated.

**Results** The obese group had a higher end-diastolic septal and posterior wall thickness and left ventricular mass index than the non-obese group. Body mass index, mid-arm and hip circumference values showed significant correlations with these echocardiographic variables. Systolic and diastolic functions of the left ventricle were normal in both groups, although stroke volume was high in the obese group. The right ventricle tissue Doppler parameters were similar in both groups. However, the S wave of the septal/lateral tricuspid valve annulus was reduced in the obese group, but not to the level reflecting systolic dysfunction. This was inversely correlated with hip, waist, and mid-arm circumference. Stepwise multiple regression analysis showed that the mid-arm and hip circumferences followed by the body mass index are significant predictors of these early cardiac abnormalities.

**Conclusion** Left ventricular hypertrophy is present in obese children, although both systolic and diastolic functions are normal. Tissue Doppler imaging revealed a minor, but still significant, reduction in the right ventricular systolic function.

**1676 LOW DOSE OXYBUTININ IN CHILDHOOD NOCTURNAL ENURESIS**

M Naseri. Mashhad University of Medical Sciences, Mashhad, Iran

**Objective** To evaluate response to low dose oxybutynin in children with nocturnal enuresis.

**Materials and Methods** Forty one out of 111 neurologically normal enuretic children who referred nephrology clinic in a 3- year period (2007–2009) received low dose oxybutynin (2.5–10 mg/day depending on the age) to define response to the drug in one and 3- month periods. No response, partial and full responses were defined as decreased in bed wetting in the rate of 0–49%, 50–89% and ≥90% respectively.

**Results** In first month of treatment, full, partial and no responses were reported in 3 (7.3%), 14 (34.1%) and 24 (58.6%) patients respectively. In non-responder patients 6 (25%) and 5 (20.8%) (patients had full and partial responses in 3-month period, whereas 13 (54.2%) had no response. Side effects of the drug were reported in 5 (12.2%) patients. Children with non-mono symptomatic nocturnal enuresis presented a better response to the drug than those with mono symptomatic nocturnal enuresis (75% versus 25%). There was no significant differences between age, gender, family history of enuresis and presence of absence of daytime urinary or bowel symptoms in responder and non-responder groups (<p>0.05 for all).

**Conclusion** In the present study which is a clinical report study with no control group, there was 68.3% treatment benefit and 12% risk (side effects of the drug) with low dose oxybutynin, so it may have a role in treating nocturnal enuresis especially patients with NMNE who experience adverse effects of the drug with standard treatment.

**1677 MONOSYMPTOMATIC AND NON-MONO SYMPTOMATIC NOCTURNAL ENURESIS: A CLINICAL EVALUATION**

1 M Naseri, 1 M Hirdfar, Mashhad University of Medical Sciences; 2 Pediatric Surgery, Mashhad University of Medical Sciences, Mashhad, Iran

**Background** Nocturnal enuresis is divided into mono-symptomatic nocturnal enuresis) NMNE) and non mono-symptomatic nocturnal enuresis) NMNE. (This study was conducted to review clinical and ultrasonography findings in enuretic children, and compare organic and functional pathologies of lower urinary tract (LUT) in children with mono-MNE with those who have NMNE.

**Methods** 111 neurologically normal children with chief complaint of enuresis enrolled in the study including 60 boys and 51 girls, aged 5–17 years old, 43 (38.8%) with MNE and 68 (61.2%) with NMNE.

Urine analysis, urine culture and kidney-bladder ultrasound sonography was done for all. Some patients underwent voiding cystoureterography (VCUG), urodynamics study (UDS), or both.

**Results** Patients were divided into 3 groups: MNE, NMNE -day time incontinence and NMNE+daytime incontinence. Constipation, encopresis and urge incontinence were significantly more frequent in patients with NMNE+daytime incontinence (<p>0.011, 0.005, 0.001 respectively). Bladder wall thickness was the most common US findings. One patient with MNE and 9 with NMNE+daytime incontinence had vesico-ureteral reflux (VUR) (<p=0.016). Posterior urethral valve was reported in one patient with NMNE. Evidences of bladder dysfunction were noted in about half of the patients who underwent UDS, with higher prevalence in cases with NMNE+daytime urinary incontinence (<p=0.297). Bowel symptoms and VUR were significantly more prevalent in cases with NMNE+daytime incontinence.

**Conclusion** We recommend doing VCUG in enuretic children who have daytime incontinence. In addition our study revealed that symptoms suggestive of over active bladder are not good indicators for bladder dysfunction.

**1678 TREATMENT OF INFANTILE COLIC WITH LACTOBACILLUS REUTERI AND THE RELATIONSHIP WITH POSTPARTUM DEPRESSION: A RANDOMIZED CONTROLLED TRIAL STUDY**

N Karadag, D Dili, A Dursun, B Karagol, N Hakan, A Kundak, S Beken, A Zenciroglu, N Okumus. Dr Sani Ulus Maternity, Childrens Education and Research Hospital, Division of Neonatology, Ankara, Turkey

**Background and Aim** Infantile colic (IC) is a common behavioural syndrome within the first 3 months of life. We aimed to compare the effectiveness of Lactobacillus reuteri (L.reuteri) and herbal drop combined with baby massage on IC and to evaluate the relationship with postpartum depression and anxiety.

**Methods** Wessel Criteria were used for the diagnosis of IC in otherwise healty newborns. Patients were randomized into three groups: Group-1: L. Reuteri DSM17938 (BioGaia AB, Stockholm, Sweden), Group-2: Herbal drop (Babs, BerkoAB, İstanbul, Turkey), Group-3: Sterile water. All groups had baby massage. Infants crying episodes, feeding and stooling characteristics, growth, weight gain were noted weekly. Emotional structures of mother’s behaviour were evaluated before and at 2nd month with Edinburgh postpartum depression scale (EPDS) and State Trait Anxiety Inventory (STAI) tests.

**Results** Seventy-four infants and their mothers completed the trial: 25 in the probiotic group, 24 in herbal drop, and 25 in placebo group. There was no difference between groups in demographic and clinical characteristics. The male rate was 62.2% (n=46). Crying times(minutes/day) at admission were similar (Group1: 54±8, Group2: 55±9, Group3: 54±8, <p=0.67). A significant decrease in crying times were seen at 3 week in group1 (Group1: 55±9, Group2: 50±6, Group3: 18±4, <p=0.001). The weight gain at this time was in group1 better, too (<p=0.001). High EPDS and STAI scores decreased significantly after treatment in group1 at 2 month (<p=0.001). No adverse effects were reported in our groups.

**Conclusion** The emotional structure and anxiety level of mothers affects the behaviour of infants. L. reuteri, reduced the crying episodes, mothers anxiety and postpartum depression and can be used in treatment of infantile colic.
