Method A total of 50 mothers who have hospitalized infants in NICU, included in this study and the social support they perceived, and the their anxiety and depression levels were analyzed using “Multidimensional Scale of Perceived Social Support Scale” and Hospital Anxiety and Depression Scale (HAD scale), respectively.

Results Perceptions of total social support and the social support provided by friends in the mothers increased as the infants’ birth weight decreased; the levels of total perceived social support and the perceived social support from families and spouses in the mothers getting pregnant with assisted conception techniques (ACT) were greater, compared with the mothers of spontaneous conception. The scores of total perceived social support and the perceived social support from families and spouses in depressed mothers were found to be lower than those in otherwise healthy mothers.

Conclusion It was concluded in our study that the mothers of the hospitalized infants in the neonatal intensive care unit required social support provided especially by the spouses and the families, disclosing the relationship of inadequate perception of such supports with development of depression.

1766 DO WE REALLY NEED TO REQUEST THAT BLOOD INVESTIGATION?

doi:10.1136/archdischild-2012-302724.1765

Blood investigations form an important aspect of patient management. Rationalisation of every test requested is needed to ensure optimum use of available resources. Wide variation in estimates of inappropriate laboratory use (4.5–95%) has been reported in literature. Hospitalisation beyond 7 days, complex cases, level of staff training, lack of awareness of costs are factors contributing to laboratory over utilisation.

We assessed our blood investigation ordering practices in order to evaluate unnecessary investigations and clinical variance. We aimed to develop a standard framework for ordering investigations in preterm babies.

This retrospective study (Jan-June 2010) evaluated blood investigations requested in first 14 days of life on all the babies born <30 weeks gestation and admitted to our neonatal unit. These data amounted to ~5% of bed days on the unit over the study period. We created a standard investigation model for preterm babies and compared the findings with the standard.

37 babies were included in the study with total 479 cot days which represent 4.3% of bed days on the unit over the study period.

Conclusions The external data safety monitoring committee recommended stopping recruitment after analyzing data from 59 infants due to a significant difference in primary outcome between the groups. We present data for 72 infants enrolled when this recommendation was made. Fewer infants randomised to EM had temperatures within the target range [41% vs 77%, p=0.002] and more had admission temperature >37.5°C [46% vs 17%, p=0.009].
