Conclusions: Severe ROP remains a strong marker of childhood disabilities in a recent and large international cohort of infants ≤1250 g BW.

THE ASSOCIATION BETWEEN PRETERM BIRTH AND AUTISM COULD BE EXPLAINED BY MATERNAL AND NEONATAL MORBIDITY

S Johansson, S Buchmayer, A Johansson, C Hultman, P Sparen, S Cnattingius.
Karolinska Institutet, Stockholm, Sweden

Background and Aims: Children born preterm face an increased risk of autistic disorders.

We examined whether the association between preterm birth and risk of autistic disorders could be explained by pregnancy complications or neonatal morbidity.

Methods: Swedish, population-based, case-control study including 1216 cases with autistic disorders born between 1987 and 2002, and 6080 controls matched with respect to gender, birth year, and birth hospital. Associations between gestational age and autistic disorders were assessed and adjusted for maternal, birth and neonatal characteristics.

Results: Compared with infants born at term, the unadjusted odds ratios (ORs) for autistic disorders among very and moderately preterm infants were 2.05 [95% CI: 1.26–3.34] and 1.55 [95% CI: 1.22–1.96], respectively.

In analyses controlled for maternal, pregnancy, and birth characteristics, ORs were reduced to 1.48 [95% CI: 0.77–2.84] and 1.35 [95% CI: 0.98–1.81], respectively.

Adding also neonatal complications to the analyses, ORs were 0.98 [95% CI: 0.45–2.16] and 1.25 [95% CI: 0.90–1.75], respectively.

Conclusions: The increased risk of autistic disorders related to preterm birth is mediated primarily by prenatal and neonatal complications.

THE PROGNOSTIC VALUE OF AEEG AND NIRS DURING THERAPEUTIC HYPOTHERMIA IN TERM ASPHYXIATED NEWBORNS

C Niezen, A Bos, D Sival, H ter Horst. Pediatrics, University Medical Center Groningen, Groningen, The Netherlands

Background and objective: Infants with hypoxic-ischemic encephalopathy (HIE) are treated with therapeutic hypothermia (HT). Perinatal asphyxia amplitude-integrated EEG (aEEG) and near-infrared spectroscopy (NIRS) are used to determine prognosis. We aimed to assess the prognostic value of aEEG and NIRS during HT.

Methods: 40 term infants with HIE and treated with HT were retrospectively studied. aEEG and NIRS were started immediately after admission. aEEGs were assessed by pattern recognition: background pattern (BP), presence of sleep wake cycling (SWC) and epileptic activity (EA) were appraised. Recordings during HT (72 hrs) were analysed.

Results: 84% of infants had an abnormal BP (discontinuous normal voltage, burst suppression (BS), continuous low voltage (CLV) or flat trace (FT)) at admission. The LR+ (95% CI) of an severely abnormal BP (BS, CLV, FT) for mortality was 1.97 (1.24–3.12) at 6h after birth and increased to 4.5 (3.16–6.39) at 24h, 6.3 (2.04–19.4) at 48h and 6.19 (1.93–19.8) at 72h. LR+ of BS for mortality was below 1 at any time. LR+ of EA for mortality was 4.95 (2.20–11.1). the type of EA (e.g. status epilepticus) was not predictive. LR+ of SWC for survival was 10.7 (1.62–70). ReSO2 increased from 0 to 72h after birth, but was not different at any time between infants that died or survived.

objective: To determine if the rapid rise in serum sodium or rapid correction of hypernatremia predict the composite outcome of severe IVH (grade 3 and 4) or death during the first 10 days of life.

Methods: Single center retrospective review of 167 preterm infants with GA ≤26 weeks who had serum sodium monitored at least every 12–24 hours and more frequently, if indicated. Logistic regression analysis identified which of the commonly cited risk factors of HIE, including rapid (≥10 and >15 mmol/l/day) rise or fall in serum sodium could predict composite outcome in hypernatremic infants.

Results: 98 (59%) of 167 infants studied developed hypernatremia (serum sodium ≥150 mmol/L), with a maximum median serum sodium of 154 mmol/l (range 150–181, IQR 152–157), occurring on median postnatal age of 4 days (IQR 3–5). Grade 4 IVH was more frequent in hypernatremic compared to normonatremic infants (p=0.032, OR 3.4, 95% CI 1.1–10.6). Among 98 infants with hypernatremia, severe IVH or death occurred in 33 and 21 infants with rapid (≥10 mmol/l/day) rise and drop in serum sodium, respectively. However, rapid (>10 and >15 mmol/l/day) rise or fall in serum sodium was not associated with composite outcome on multivariate analysis.

Conclusion: Correction of hypernatremia not exceeding 10 to 15 mmol/l/day in hypernatremic preterm infants was not associated with severe IVH or death.

AUTOMATIC IDENTIFICATION OF ACTIVITY BURSTS IN EEG OF PRETERM INFANTS

K Murphy, R Goulding, N Stevenson, GB Boylan. Paediatrics and Child Health, University College Cork, Cork, Ireland

Background: EEG monitoring provides important information about the neurological status of the preterm infant but is difficult to interpret for most. We aim to automatically detect the typical bursting pattern (trace discontinu) of the preterm EEG and compare the detections with expert manual annotations.

Methods: The method was based on the single channel EEG method of Palmu et al. but extended to 8-channel recordings for the first time. The EEG signal was first filtered with a Kaiser-window filter and the output of a non-linear energy operator (NLEO) was calculated. The NLEO signal was smoothed and corrected for baseline artefacts. A burst was identified if the resulting signal remained above a threshold, X, for T time samples: X ≥ Xs for T samples. The threshold was calculated as: Xs = X + k * SD, where k is 0.5. The time-continuous trace was divided into 4-second epochs starting at each burst occurrence time.
Abstracts

above 1.5µV² for longer than 1s. Each EEG channel was processed separately and the final outcome was considered to be an activity burst if a burst was detected in 2 or more channels.

The method was tested on a database of 24 babies born before 30 weeks gestation (avg 26.5 ± 1.7 weeks). For each baby 10 minutes of 8-channel EEG signal was analysed.

**Results**

Agreement with the expert burst annotations was on average 77.2% over the 24 subjects (Min:59.6%, Max:90.3%, std-dev:8.5%). Most errors consisted of disagreement over the precise start and end points of a burst.

**Conclusions**

Automatic burst detection has been applied for the first time to a large database of preterm 8-channel EEG. Promising results were obtained for automated EEG interpretation. Future work will attempt to reduce the error by use of more sophisticated methods to merge the per-channel detections.

**334 RELATIONSHIP BETWEEN ACUTE KIDNEY INJURY (AKI) USING AKI NETWORK CRITERIA AND BRAIN MRI FINDINGS IN ASPHYXIATED NEWBORNS AFTER THERAPEUTIC HYPOThERMIA**

doi:10.1136/archdischild-2012-302724.0334

S Sarkar, B Jordan, Bhagat, JR Bapuraj, RA Deichert, D Selewska. Department of Pediatrics, Division of Neonatal-Perinatal Medicine, University of Michigan Health System; Pediatrics, St Joseph Mercy Hospital; Department of Radiology; Department of Pediatrics, Division of Pediatric Nephrology, University of Michigan Health System, Ann Arbor, MI, USA

We hypothesized that hypoxic-ischemic lesion on brain MRI would differ between infants with AKI compared to those without AKI following cooling.

**Methods**

88 consecutively cooled infants who had brain MRI were reviewed. All infants had renal function assessed before the start of cooling (baseline); at 24, 48, and 72h through cooling; and then on day 5 or 7 of life. Injuries to both basal nuclei and cortex on MRI were considered severely abnormal.

**Results**

AKI was found in 34 (39%) of 88 infants with 15, 7, and 12 fulfilling AKI network criteria for stage I, II, and III, respectively. Hypoxic-ischemic lesion on brain MRI was present in 50 infants. In 26 infants (AKI 14, no AKI 12), MRI was severely abnormal.

Abnormal MRI was more frequent in the AKI group (AKI 25 of 34, 75% versus No AKI 25 of 54, 46%, p=0.012, OR 3.2, 95% CI 1.3–8.2). Multivariate analysis identified only the AKI (p=0.032, OR 2.9, 95% CI 1.1–7.6), and chest compression for resuscitation to be independently associated with primary outcome.

Severely abnormal MRI were similar between infants with stage III and stage II AKI (stage III 3 of 12, 25% versus stage II 3 of 7, 43%; p=0.617), or stage I AKI (stage III 3 of 12, 25% versus stage I 8 of 15, 53%; p=0.238).

**Conclusions**

AKI is independently associated with the presence of hypoxic-ischemic lesions on post-cooling brain MRI. However, the severity of AKI did not correlate with the severity of brain MRI abnormalities.

**335 BRAIN PLASTICITY AFTER PRETERM BIRTH: AN EEG STUDY OF AUDITORY PROCESSING**

doi:10.1136/archdischild-2012-302724.0335

A Darque, RH Leuchter, TA Rihs, FA Lazeyras, CB Caballero, CM Michel, PS Hüppi. Department of Pediatrics, University Hospitals of Geneva; Functional Brain Mapping Laboratory, Dept of Fundamental Neurosciences, University of Geneva; Department of Radiology, University Hospitals of Geneva, Geneva, Switzerland

**Background and Aims**

Premature birth has an impact on brain maturation that can be measured at term equivalent age (TEA) with neuroimaging techniques. The aim of our study is to determine the neural pathways and processes that are activated in term babies and preterm infants (GA < 32wks) at term after listening to their mother’s voice and a stranger’s voice with EEG and fMRI techniques. Our secondary aim is to differentiate innate (genetically determined) and acquired (determined by experience) networks. Here we present the results of the EEG analysis of the preterm recordings.

**Methods**

High-density (109-channel) recordings were performed for subsequent event-related potentials (ERP) analysis on newborns while listening to their mother’s voice and the voice of an unknown woman saying a short phrase. Two groups were tested: premature newborns tested at TEA (GA:28.7wks) and full term controls (GA:40wks).

**Results**

For preterm babies, the ERP results showed significant differences on left temporal electrodes when they listened to their mother’s voice compared to a stranger’s voice with an increased negativity at 100ms post voice onset (t-test; p<0.05). At later stages of voice processing, significant differences were found between 220–320ms with increased positivity for the mothers voice over right temporal electrodes.

**Conclusions**

By showing specific activation in preterm babies at term when they listen to their mother’s voice, our results suggest that the maturation of the auditory network can be influenced by these early experiences resulting in an early differentiation between their mother’s voice and the voice of a stranger.

**336 ARTERIAL SPIN LABELING MAGNETIC RESONANCE IMAGING TO EVALUATE PERINATAL ARTERIAL ISCHEMIC STROKE**

doi:10.1136/archdischild-2012-302724.0336

JB De Vis, KJ Kersbergen, ET Petersen, AH Hendrikse, F Groenendaal, LS de Vries, MJNL Benders. Radiology, University Medical Center Utrecht; Neonatology, Wilhelmina Children’s Hospital/UMCU, Utrecht, The Netherlands

**Background and Aim**

Studies performed in infants with perinatal arterial ischemic stroke (PAIS) have shown relations between initial neuro-imaging and neurodevelopmental outcome. However, not all variation in outcome can be explained. It is known from adult stroke studies that (luxury) perfusion of the stroke area is related to outcome. In this study, Arterial Spin Labeling (ASL) MR imaging was used to evaluate (luxury) perfusion in infants with PAIS.

**Methods**

Conventional and ASL MR images (3T) were acquired of three PAIS patients 3–5 days after the ischemic event. Near Infrared Spectroscopy was used to monitor cerebral oxygenation. Follow-up MR imaging was conducted 2–16 weeks after the event.

**Results**

A lower perfusion signal was measured in all infants in the area corresponding with the diffusion-restricted area on the diffusion-weighted images. Furthermore, in one infant, luxury perfusion was visualised in the cortex of the affected area. Measurements of volume flow (Phase-Contrast MR Angiography) and cerebral oxygenation were in agreement with this, suggesting an ischemia-induced vasodilatation. Follow-up ASL MR images in this infant showed a partly recovered perfusion. Initial [fig. 1A] and follow-up ASL images [fig. 1B] of this infant are shown.
