Recent advances in adolescent health: implications for policies and programmes

The health of adolescents is central to public health. Directing resources to health during the adolescent years is essential for building on investments made during the first decade of life, for ameliorating problems that may arise during these early years of childhood, for transitions to adulthood and for health in the future, for this generation and the next. Significant progress has been made in understanding health and development during the second decade. This includes improved estimates of the health status of adolescents: mortality, disability adjusted life years lost and the initiation of health-related behaviours; clarity about the determinants that underlie adolescent health and disease; insights into the links between the developmental processes taking place during adolescence and health problems and health-related behaviours and conditions; and a much stronger evidence base for a range of interventions that can have a positive impact on adolescents’ health.

The presentation will outline some of the major implications of this increased knowledge for policies and programmes, drawing particularly from the recent WHO publication “Health for the World’s Adolescents: a second chance in the second decade”. It will provide an overview of how recent advances confirm, correct and challenge existing policies and programmes, and outline some of the opportunities and challenges for ensuring that what is known influences what is done to improve and maintain the health of adolescents.

Brain

Intracranial Pressure (ICP) is derived from cerebral blood and CSF circulatory dynamics, in pathology having also strong component related to volumetric changes in brain tissue or lesions. It can be affected in a course of many diseases of central nervous system. Monitoring of ICP requires an invasive transducer, although some attempts to measure it non-invasively have been made. Because of its dynamic nature, instant CSF pressure measurement using the height of a fluid column via lumbar puncture can be affected in a course of many diseases of central nervous system. Monitoring of ICP requires an invasive transducer, although some attempts to measure it non-invasively have been made. Because of its dynamic nature, instant CSF pressure measurement using the height of a fluid column via lumbar puncture is not a reliable method of monitoring ICP. The method is not suitable for monitoring ICP in patients with subarachnoid haemorrhage, stroke, intracerebral haematoma, meningitis, acute liver failure, hydrocephalus, benign intracranial hypertension, craniosynostosis, etc. Information which can be derived from ICP and its waveforms include cerebral perfusion pressure, regulation of cerebral blood flow and volume, CSF absorption capacity, brain compensatory reserve, content of vasogenic events. Some of these parameters allows prognosis of survival following head injury and optimisation of ‘CPP-guided therapy’.

Bronchopulmonary Dysplasia

Components of primary outcome

- Death at <36 wk of gestational age
- Survivors with BPD

**Results** We randomly assigned 863 infants during the first 12 h of life in 40 centres in 9 countries to inhaled budesonide or placebo. In 7 infants consent was withdrawn. Of the 437 infants assigned to inhaled budesonide, 175 died or survived with BPD.
