activated microglia populated the area in which neurons had disappeared.

Conclusions Acute development of NEC is associated with neuronal loss, microglial activation, and increased IL-8 levels in the hippocampus of preterm pigs. Gut inflammatory disorders and increased intestinal permeability may affect the immature brain and contribute to long term neurological disorders.

O-216 MELATONINE REDUCES BBB BREAKDOWN IN A RAT MODEL OF NEONATAL EXCITOTOXIC DAMAGE

Objective The Blood-brain barrier (BBB) is a complex structure that protects the central nervous system (CNS) extracellular fluid from peripheral insults. Understanding the molecular basis and functioning of the BBB has a significant potential for future strategies to prevent and treat neurological disorders. The aim of our study was (1) to investigate BBB alterations in an excitotoxic model and (2) to test the protective properties of melatonin.

Methods The glutamate analogue ibotenate was injected intracerebrally in postnatal day 5 (P5) rat pups to mimic excitotoxic injury. Rats were sacrificed at P5+2 h, P5+4 h, P5+18 h. Lesion size and location of tight junction (TJ) proteins were determined by immunohistochemistry and BBB leakage after ibotenate injection by dextran staining. BBB proteins gene expression (TJ's efflux transporters and detoxification enzymes) was determined on cortex and plexus. A group of pups was treated with melatonin (5 mg/kg, intraperitoneal).

Results Dextran extravasation was found 2 h after the insult, suggesting a rapid BBB breakdown that resolved at +4 h. A significant reduction in extravasation was observed in melatonin-treated pups. Molecular Biology, immunohistochemistry and electron microscopy showed a dynamic BBB modification during the first 4 h, partially reversed with melatonin. Lesion size evaluation confirmed melatonin white matter neuroprotection.

O-217 ASSESSMENT OF MYOCARDIAL FUNCTION IN PRETERM INFANTS WITH CHRONIC LUNG DISEASE USING TISSUE DOPPLER IMAGING

P Yajamany, RJ S Negrine, SV Rasiah, AK Ewer. Neonatology, Birmingham Women’s NHS Foundation Trust, Birmingham, UK

Background Chronic lung disease (CLD): oxygen requirement at 36 weeks corrected gestational age (CGA) is a significant neonatal morbidity which can have adverse effects on cardiac function until pre-school age.1 Conventional echocardiographic techniques such as fractional shortening (FS) and left ventricular output (LVO) may not identify cardiac dysfunction in preterm infants. We have previously demonstrated that tissue Doppler imaging (TDI) is useful in assessment of myocardial function in these patients.2

Objectives To compare myocardial function in preterm infants born at.

Methods 50 preterm infants with CLD (25 receiving low flow nasal cannula oxygen and 25 receiving non-invasive positive airway pressure) and 22 without CLD (controls) had an echocardiogram at approximately 36 weeks CGA. Myocardial function was evaluated using FS, LVO and TDI. Ethical approval and written parental consent were obtained.

Results Median GA and birth weight of infants with CLD was lower than controls (27 wk (23–31) vs. 29 wk (23–31); 829 g (500–1790) vs.1030 g (570–1700)). There was no difference in persistence of PDA, tricuspid regurgitation, left ventricular FS and LVO between the groups. However, using TDI right ventricular peak systolic (S’) and late diastolic velocities (A’) (p < 0.001) were all significantly higher in CLD cases compared with controls.

Conclusion Cardiac dysfunction in this vulnerable group of patients can be better identified with TDI compared to FS and...
