Background Recently bronchopulmonary dysplasia (BPD) occurs not infrequently without an exposure to hyperoxia and/or mechanical ventilation in very preterm infants. To simulate the recent pattern of BPD, novel animal model of BPD induced by inflammation alone is needed. We were to establish a rat model of BPD induced by postnatal systemic lipopolysaccharide (LPS) administration alone.

Methods Two days before delivery, 1 μg of LPS or vehicle (V) was injected into each amniotic sac, and after birth 0.25 mg/kg of LPS or V was injected into peritoneum of pups at P1, P3, and P5. At P7 and P14, bronchoalveolar lavage (BAL) and lung harvest were performed. BAL fluid (BALF) and peripheral blood (PB) were examined for blood cell counts and lung tissue was examined for morphometry, vascular density, neutrophil infiltration, and expressions of pro-inflammatory cytokines and angiogenic growth factors.

Results Postnatal systemic LPS significantly increased the neutrophil counts in PB, BALF and within the alveoli and expressions of pro-inflammatory cytokines and angiogenic growth factors at P7. When postnatal systemic LPS was preceded by intra-amniotic LPS administration, these findings were not observed. Postnatal systemic LPS led to significant disruption of alveolar and pulmonary vascular developments at P14.

Conclusions Early postnatal systemic LPS induced systemic and pulmonary pro-inflammatory responses and disrupted alveolar and vascular pulmonary developments. This rat model of new BPD induced by early postnatal inflammation per se without an exposure to hyperoxia can be used to test the effects of anti-inflammatory agents for BPD.

**TOTAL OXIDANT STATUS AND TOTAL ANTIOXIDANT CAPACITY IN AMNIOTIC FLUID OF LATE PRETERM INFANTS**

1Department of Pediatrics, Istanbul Medeniyet University Goztepe Education and Research Hospital, Istanbul, Turkey; 2Department of Biochemistry, Istanbul Medeniyet University Goztepe Education and Research Hospital, Istanbul, Turkey

**Background and aims** Pregnancy represents a complex state in which the mother and the fetus both contribute to the oxidative stress and production of reactive oxygen species. The ability to buffer these is called total antioxidant capacity (TAC). We aimed to evaluate whether amniotic total oxidant status (TOS) and TAC can have a role in late preterm births after premature rupture of membranes (ROM).

**Methods** The study was a prospective observational trial. Group 1 (n = 30): late preterm births with premature ROM, Group 2 (n = 30): term infants with prolonged ROM, Group 3 (n = 30): term infants born without prolonged ROM. Amniotic fluid and cord blood samples were collected during delivery and TOS (μmol H2O2 Eq/L) and TAC (μmol Trolox Eq/L) levels were measured.

**Results** Mean gestational ages were 35.3 ± 1.1; 39.29 ± 1.25; 38.7 ± 0.63 weeks respectively. Cord blood samples of the groups revealed no difference between any of the parameters checked (pH, pCO2, HCO3, lactate, Methb, TAC and TOS) (p > 0.05, for each). TAC levels of amniotic fluids (2.05 ± 0.60; 2.04 ± 0.5 and 21.89 ± 0.36) were also similar between groups (p > 0.05). But TOS levels of Group 1 was significantly higher than Group 2 (p < 0.05) and Group 3 (p < 0.01). No significant difference was detected between Group 2 and 3.

**Conclusion** Similar cord blood levels of all parameters reflect the similar perinatal conditions of infants at birth. Similar TOS levels of term groups show that there is no close relation between TOS and infectious status. But on the other hand; significantly higher TOS levels of Group 1 can be related with premature birth; which can lead us to antioxidant therapies to avoid premature birth.

**Neonatal Sepsis**

**EPIDEMIOLOGY OF NEONATAL SEPSIS IN SWITZERLAND – RESULTS FROM THE SWISS PAEDIATRIC SEPSIS STUDY**

**Background and aims** Neonatal infection is a major cause of morbidity and mortality. The ongoing Swiss Paediatric Sepsis Study prospectively evaluates the epidemiology of blood culture-proven sepsis in newborns and children in Switzerland.

**Methods** Newborn infants admitted to nine Swiss neonatal intensive care units (NICUs) and presenting with culture-proven sepsis between 9.2011–2.2014 were prospectively enrolled. Early-onset sepsis (EOS) was defined as infection occurring.

**Results** We identified 189 episodes of blood culture-proven sepsis in 186 patients. Thirty-seven episodes were classified as EOS and 152 episodes were classified as LOS. Median gestational age at birth was 34 weeks for EOS and 28 weeks for LOS. Mortality was 14% in EOS and 9% in LOS. Forty-six percent of patients required mechanical ventilation during the sepsis episode, and 4% required catecholamine treatment for arterial hypotension.

Group B Streptococcus (GBS) and Escherichia coli were the most frequently isolated pathogens in EOS, accounting for 35% and 16% of episodes. Coagulase-negative staphylococci were the leading pathogens in LOS (36%), followed by Staphylococcus aureus (18%), Escherichia coli (16%), and GBS (11%). The proportion of hospital-acquired LOS due to Coagulase-negative staphylococci, Staphylococcus aureus and Escherichia coli varied between 10–68%, 0–45% and 0–30% in different NICUs.

**Conclusions** This national study confirms that neonatal sepsis continues to cause high morbidity and significant mortality. GBS is the most common cause of EOS. There are important differences in the aetiology of LOS in different institutions.
Background Neonatal septic shock is a devastating condition associated with high morbidity and mortality.

Methods A retrospective study was conducted in children’s hospital Tunisian PICU between 2005 to 2013. All neonates (~28 days) treated for septic shock with bacterial proof were included. Nosocomial infection was an exclusion criterion. The chart review relieved demographics, length of stay, therapies and outcomes.

Results A total of 40 neonates were included. Mean age on admission was 34 h ± 3.7. Mean SNAPP score was 25 ± 17. Materno-fetal infection was observed in 37 cases, staphylococcal pneumonia in 2 cases and bacterial coinfection with bronchiolitis in the last case. The bacteriological study showed a notable predominance of streptococcus B (40%) and E.coli (35%). All patients required mechanical ventilation (mean duration: 85 ± 556 h) and haemodynamic support (mean duration 49 ± 335 h). Mortality rate was 19% in full term infants, 12.5% in near term infants and 27% in extremely preterm infants. Conclusions Our results would indicate a high mortality rate in neonatal septic shock. A goal directed therapy for septic shock, implanted in our PICU, could improve outcomes for this vulnerable population.

PS-214 DOES A TOTAL STERILE COLLECTION BUNDLE REDUCE FALSE POSITIVE BLOOD CULTURE RATES AND ANTIBIOTIC USE IN NEONATAL INTENSIVE CARE?

HE Gilian, IF Hamilton, JW Davis. Neonatal Intensive Care, St Michael’s Hospital, Bristol, UK.

Background and aim In neonatal intensive care coagulase negative Staphylococcus species can be both blood culture contaminant and pathogen. False positive cultures can result in clinical uncertainty and unnecessary antibiotic use. Our aim was to assess the effect of a total sterile blood culture collection bundle on the incidence of false positive blood cultures in a regional surgical neonatal intensive care unit.

Method Clinical data of all infants who had blood cultures taken before and after the introduction of the collection bundle (sterile technique and 2% Chlorhexidine) were collected. The rates of false positive blood cultures, defined as the presence of a skin commensal and <3 predefined clinical signs (Modi et al. 2009), were compared.

Results In total 367 blood cultures from 294 babies were assessed, 197 pre-intervention (PRE) and 170 following bundle introduction (POST). The median birth weight and gestation were similar in both groups. The rate of false positive cultures in the total PRE group was 9/197 (4.6%) compared to 1/170 (0.6%) in the POST group (p < 0.05). In infants <28 weeks the rates reduced from 4/29 (13.8%) to 0/30 (0%) (p < 0.05). Unnecessary antibiotic exposure rate was 7.7% in the PRE group versus 0.0% in the POST group (p < 0.05).

Conclusion Implementation of this collection bundle reduced the number of false positive blood culture results. This has a potential benefit in reducing unnecessary antibiotic use and associated health care costs.

PS-215 SEPSIS REDUCTION CARE BUNDLES IMPROVE COGNITIVE OUTCOME IN VERY LOW BIRTH WEIGHT INFANTS

1W Davis, 2J Lany, 3PJ Cairns, 4O Harding, 5K Lytt. 1Neonatology, St. Michael’s Hospital University Hospitals Bristol, Bristol, UK; 2Neonatal Neuroscience, University of Bristol, Bristol, UK.

Abstract PS-216 Figure 1

Background Very low birth weight (VLBW) infants with late onset sepsis have increased risk of neurodisability. Care bundles to reduce these infections in NICU are effective. The impact of care bundles on long-term neurodevelopmental outcome has not been described. We aimed to determine if implementation of a sepsis-reduction care bundle was associated with improvement in neurodevelopmental outcomes in VLBW infants.

Methods A multimodal sepsis improvement bundle was implemented in a regional NICU from July 2006. This bundle focused on hand hygiene and line care improvements. Mortality and neurological morbidity rates were compared pre and post intervention (Jan ’01 - Dec ’07 vs. Jul ‘08 – Dec ’12). Infants had neurodevelopmental assessment at 24 months corrected gestation with Bayley Scales of Infant development. Moderate cognitive disability was defined as a cognitive/language score below 2SDs, moderate motor disability as a motor score below 2SDs.

Results Birth weight, gestation and gender were similar in both cohorts. Coagulase Negative Staphylococcus septicaemia rates reduced from 7/1000 care days before implementation to 2.8/1000 in 2012. Mortality rates were similar between the groups (66/426 vs. 40/310; p = 0.3). There was no difference in moderate motor disability (17/85 vs. 3/42; p = 0.07). There was a significant reduction in moderate cognitive disability (16/86 vs. 2/44; p = 0.03) after implementation of the sepsis care bundle. Conclusions Sepsis-reduction care bundles improve the 2-year neurodevelopmental outcome of VLBW infants. The improvement seen in cognitive function is likely to translate into significantly less long-term learning disability.
