**Preterm Brain Injury – Experimental**

**PS-331** SERIAL CRANIAL ULTRASONOGRAPHY OR EARLY MRI FOR DETECTING PRETERM BRAIN INJURY?

**Background and aims** Magnetic resonance imaging (MRI) is considered imaging method of choice for high-risk preterm infants to assess brain injury. However, MRI scanning in preterm infants is particularly challenging due to safety, logistical and quality issues that limit clinical feasibility. Meanwhile, due to ongoing technical developments and by using additional acoustic windows, advanced serial cranial ultrasonography (CUS) has acquired great clinical value. We hypothesised that dedicated serial CUS is equally effective in diagnosing preterm brain damage as a routine MRI scan at 30 weeks postmenstrual age and excels in clinical feasibility.

**Methods** We prospectively collected data of 307 infants born <29 weeks gestational age. Serial CUS and MRI were performed according to standard clinical protocol. In case of instability, MRI was postponed or cancelled. Brain images were assessed by independent experts and compared between modalities.

**Results** Serial CUS was performed in all infants, MRI was often postponed (n = 58) or cancelled (n = 127). Injury was found in 146 infants (47.6%). Clinical characteristics differed significantly between groups that were subdivided according to timing of MRI. 61 discrepant imaging findings were found. MRI was superior in identifying cerebellar haemorrhages; CUS in detection of acute intraventricular haemorrhage and cerebral sinusovenous thrombosis.

**Conclusion** Advanced serial CUS seems highly effective in diagnosing preterm brain injury, but may miss cerebellar

**Evaluation of Dengue IgA and NS1 Rapid Test as an Early Diagnostic Test for Dengue Virus Infection**

**Background** Dengue is a major health problem. The lack of consensus on excellent rapid diagnostic test for early detection of dengue infection has generated interest to determine the validity of dengue IgA versus NS1 as rapid test in the early diagnosis of dengue with hemagglutination inhibition (HI) as standard reference among paediatric patients up to <19 years old seen at a private hospital from March, 1, 2012 to October, 30, 2012.

**Methods** Paired serum samples were examined from 51 patients suspected of dengue with fever of not more than 7 days. There were 29 males and 22 females. Initial blood samples were collected on the first day of consult and tested for IgA, NS1, and HI. Second blood samples for HI were collected 7 days after the initial extraction.

**Results** From 51 samples, sensitivity of dengue IgA was 80% with 95% CI (70–90) while specificity was at 50% with 95% CI (36–64) versus NS1 which showed sensitivity of 27% with 95% CI (15–39) and specificity of 67% with 95% CI (54–86). IgA rapid test demonstrated 71% positivity in detecting acute primary dengue infection and 82% for acute secondary dengue infection. NS1 detected 43% of primary dengue infection and 24% of secondary dengue infection.

**Conclusions** Dengue IgA was more sensitive for early diagnosis of dengue and had better performance in detecting primary and secondary of dengue than NS1.

abnormalities. Although MRI does identify these lesions, clinical additional value is limited. Improved safety, better availability and tailored procedures are essential for MRI to increase its value in clinical care.

**BRAIN TISSUE VOLUMES AT TERM-EQUIVALENT AGE IN PRETERM INFANTS: BIOMARKER FOR NEURODEVELOPMENTAL OUTCOME UNTIL 5 YEARS OF AGE**

K. Keunen, *B.J.M. Kooij van*, *A. Bergström*, *A. Rosenørn*, *A.D. Andersen*, *T. Thymann*, *S. Kaalund*, *E. van der Beek*, *P. Sangild*. Clinical and Experimental Nutrition, University of Copenhagen, Frederiksberg C, Denmark; Early Life Nutrition, Danone Nutricia, Singapore, Singapore

**Methods**

108 preterm infants (median GA 28.6 weeks; 25.0–30.9 weeks) were prospectively studied at TEA (median 41.6 weeks PMA; 39.7–43.6). Volumes of eight different tissue types were quantified using an automatic segmentation method (Anbeek, PLOSOne2013) and related to neurodevelopmental outcome using cognitive (CCs), fine motor (FMss), and gross motor scaled scores (GMss) of the BSITD-III at two years corrected age, Griffiths Mental Development Scales (DQ) at age 3.5, and WPPSI at age 5.5. Corrections were made for PMA at scan, intracranial volume and maternal education.

**Results**

Significant results are presented in the table. Both ventricular (Vent) and cortical grey matter volume (CoGM) were inversely related to all included subscales of the BSITD-III and DQ. However, the association at age 3.5 was lost after excluding infants with severe brain lesions (venous infarction, PHVD) with neurosurgical intervention, and severe cerebellar haemorrhages. CoGM volume demonstrated a borderline significant inverse correlation with periformal IQ at age 5.5 (coeficient-3.2; -6.6–0.08), that did not change after adjustment for severe brain lesions. Cerebellar volume was related to cognitive outcome at 2 and 3.5 years, but the association was mediated by cerebellar injury.

**Conclusion**

Vent and CoGM volumes at TEA may serve as biomarkers for long-term neurodevelopmental outcome in preterm infants. The relationship between larger CoGM volumes and adverse neurodevelopment may reflect disturbances in white matter-CoGM boundaries and warrants further investigation.

**DO CLINICAL RISK FACTORS AFFECT WHITE MATTER MICROSTRUCTURAL INTEGRITY (FA) AT TERM EQUIVALENT AGE IN A MULTI-CENTRE COHORT OF PRETERM NEONATES?**

J. Schuurmans, *K. Keunen*, *G. Groenendaal*, *A. Leemans*, *MA Viergever*, *K. Keunen*, *V. Fellman*, *AC Berg*, *T. van Bel*, *LS de Vries*, *MN. Benders*. Perinatology, Wilhelmina Children’s Hospital University Medical Center Utrecht, Utrecht, Netherlands; Image Sciences Institute, University Medical Center Utrecht, Utrecht, Netherlands; Pediatrics, Lund University and Södertörn University Hospital Helsinki University, Lund Helsinki, Sweden; Pediatrics, Lund University and Skåne University Hospital, Lund, Sweden; Centre for the Developing Brain, Wilhelmina Children’s Hospital University Medical Center Utrecht King’s College London, Utrecht, Netherlands.

**Background and aims**

We aimed to investigate the effect of clinical risk factors on white matter structural integrity at term equivalent age (TEA), as measured by fractional anisotropy (FA).

**Methods**

Diffusion tensor imaging of sufficient quality was available for 182 infants (gestational age (GA) <28 weeks), scanned at TEA in two centres. FA values of 14 regions (posterior limb of the internal capsule (PLIC), cerebral peduncles, corpus callosum, sagittal stratum, superior/posterior corona radiata, posterior thalamic radiation, left and right side for all) were automatically calculated (ExploreDTI, Leemans SBRMN 2009) using an atlas-based approach (Oishi, NeuroImage 2011). Subjects with overt parenchymal injury were excluded. Clinical characteristics tested against FA in the multivariable linear regression analysis for each region were GA, gender, intra-uterine growth retardation (IUGR), hypotension, mechanical ventilation >7 days, morphine (yes/no), post-haemorrhagic ventricular dilatation (PHVD), surgery, postmenstrual age at scanning (PMA) and participating centre. A cut-off value of p < 0.004 (0.05/14) was used to correct for multiple comparison.

**Results**

Statistically significant positive associations with FA were found for PMA in PLIC (right), Superior Corona Radiata and Posterior Corona Radiata (left) and GA in Corpus Callosum, Sagittal Stratum (left), Posterior Thalamic Radiation (left). Statistically significant negative associations with FA were found for Surgery in Sagittal Stratum (right) and IUGR in Posterior Thalamic Radiation (left). Centre was significantly associated with FA in 8/14 brain regions.

**Conclusion**

The microstructure of the preterm brain at TEA depends on GA and PMA at scan, IUGR and surgery. A possible interaction between surgery and morphine warrants further investigation.
