abnormalities. Although MRI does identify these lesions, clinical additional value is limited. Improved safety, better availability and tailored procedures are essential for MRI to increase its value in clinical care.

Objectives To assess the association of brain tissue volumes at term-equivalent age (TEA) with long-term neurodevelopment.

Methods 108 preterm infants (median GA 28.6 weeks; 25.0–30.9 weeks) were prospectively studied at TEA (median 41.6 weeks PMA; 39.7–43.6). Volumes of eight different tissue types were quantified using an automatic segmentation method (Anbeek, PLOSOne2013) and related to neurodevelopmental outcome using cognitive (CCs), fine motor (FMss), and gross motor scaled scores (GMss) of the BSITD-III at two years corrected age, Griffiths Mental Development Scales (DQ) at age 3.5, and WPPSI at age 5.5. Corrections were made for PMA at scan, intracranial volume and maternal education.

Results Significant results are presented in the table. Both ventricular (Vent) and cortical grey matter volume (CoGM) were inversely related to all included subscales of the BSITD-III and DQ. However, the association at age 3.5 was lost after excluding infants with severe brain lesions (venous infarction, PHVD with neurosurgical intervention, and severe cerebellar haemorrhages). CoGM volume demonstrated a borderline significant inverse correlation with periformal IQ at age 5.5 (coefficient-3.2; -6.6-0.8), that did not change after adjustment for severe brain lesions. Cerebellar volume was related to cognitive outcome at 2 and 3.5 years, but the association was mediated by cerebellar injury.

Conclusion Vent and CoGM volumes at TEA may serve as biomarkers for long-term neurodevelopmental outcome in preterm infants. The relationship between larger CoGM volumes and adverse neurodevelopment may reflect disturbances in white matter-CoGM boundaries and warrants further investigation.

**Background and aims** We aimed to investigate the effect of clinical risk factors on white matter structural integrity at term equivalent age (TEA), as measured by fractional anisotropy (FA).

**Methods** Diffusion tensor imaging of sufficient quality was available for 182 infants (gestational age (GA) <28 weeks), scanned at TEA in two centres. FA values of 14 regions (posterior limb of the internal capsule (PLIC), cerebral peduncles, corpus callosum, sagittal stratum, superior/posterior corona radiata, posterior thalamic radiation, left and right side for all) were automatically calculated (ExploreDTI, Leemans ISMRN 2009) using an atlas-based approach (Oishi, NeuroImage 2011). Subjects with overt parenchymal injury were excluded. Clinical characteristics tested against FA in the multivariable linear regression analysis for each region were GA, gender, intra-uterine growth retardation (IUGR), hypotension, mechanical ventilation >7 days, morphine (yes/no), post-haemorrhagic ventricular dilatation (PHVD), surgery, postmenstrual age at scanning (PMA) and participating centre. A cut-off value of p < 0.004 (0.05/14) was used to correct for multiple comparison.

**Results** Statistically significant positive associations with FA were found for PMA in PLIC (right), Superior Corona Radiata and Posterior Corona Radiata (left) and GA in Corpus Callosum, Sagittal Stratum (left), Posterior Thalamic Radiation (left). Statistically significant negative associations with FA were found for Surgery in Sagittal Stratum (right) and IUGR in Posterior Thalamic Radiation (left). Centre was significantly associated with FA in 8/14 brain regions.

**Conclusion** The microstructure of the preterm brain at TEA depends on GA and PMA at scan, IUGR and surgery. A possible interaction between surgery and morphine warrants further investigation.

**Background and aims** Neurodevelopmental sequelae of premature birth involve cognitive and motor deficits, often persisting into adult life. The molecular mechanisms involved remain yet to be elucidated, but certain regions e.g. cerebellum and neocortex appear particularly sensitive. The current study aimed to evaluate the relevance of Brain derived neurotrophic factor (BDNF), involved in the formation of synaptic connections, and Sonic Hedghog (SHH), important for perinatal neuronal differentiation, as potential biomarkers of brain development.

**Methods** Piglets were born via planned C-section either at full term (gestational age 118d) or 12 days preterm. Euthanization and brain dissection was performed at postnatal day 5 (n = 11, n = 33) and day 26 (n = 22, n = 18), for terms and preterms respectively. BDNF and SHH levels were analysed by ELISA in pig cerebellar homogenates. Western blotting (WB) of downstream targets for BDNF (TrkB) and SHH (Patched, Smoothed, Gli-1) were included together with qPCR-array of 84 genes.
neurogenesis pathway related genes (including Bdnf and Shh) on
cerebellar and prefrontal cortical tissue.

Results Overall BDNF analysis showed no differences between
term and preterm brains but levels were significantly different
between day 5 and 26 in preterms only. SHH appeared to be
lower in preterms compared to terms, but only significantly on
Day 26.

Conclusions The reduced levels of SHH, specifically at day 26,
suggest that SHH may be a useful biomarker for delayed brain
development and indicate that the pig may provide a relevant
model to study the premature brain.

PS-335 PRETERM AND TERM PIGLETS SHOW SIMILAR
POSTNATAL ELECTROENCEPHALOGRAPHY (EEG)

Background Electroencephalography (EEG) changes rapidly
with maturation of the brain in preterm infants. Amplitude-inte-
grated EEG (aEEG) becomes more continuous, bandwidth nar-
rrows, and frequencies switch towards faster rhythms, as the
child grows older. In preterm infants with brain damage this
maturation is typically delayed. We are in the process of devel-
oping a preterm piglet brain model. Here we present the results
of the EEG as a measurement of brain development in 1–11-
day-old preterm and term piglets.

Methods One hour of EEG was recorded in 31 preterm piglets
aged 1, 2, 4 and 11 days and in 10 term piglets aged 2 and 11
days. All piglets were delivered by C-section at either 90% or
100% gestation. Upper and lower margins of the aEEG band
were visually identified and bandwidth calculated as the differ-
ence between the two values. Spectral analysis of the raw EEG
was used to determine the relative power in the delta-(0.5–3
Hz), theta-(4–7.5 Hz), alpha-(8–12.5 Hz), and beta-(13–30 Hz)
bands. General linear models were used with term vs. preterm,
and age as predictors.

Results All aEEGs were continuous. The overall means (SD) of
upper and lower margin, and bandwidth were 7 mcV (1.7), 15
mcV (5.7), and 8 mcV (4.3). Upper, lower margin, bandwidth,
alpha, beta and delta bands were unaffected by the predictors
whereas the theta band was negatively correlated to age.

Conclusions The preterm piglet EEG was continuous already 10
days prior to term. Thus, maturation of EEG was neither seen in
preterm nor term piglets and EEG may not be useful for study-
ing perinatal brain maturation.

PS-336 INFLUENCE OF N-ACETYLCYSTEINE AMIDE (NACA)
ON THE INFLAMMASOME PATHWAY. A STUDY ON
NEONATAL PIGS

Background and aims Severe perinatal hypoxia contributes to
approximately 6% of spastic cerebral palsy (CP). Studies have
indicated an association between elevation of IL-1beta after peri-
natal asphyxia and the development of CP. The NLRP3 Inflam-
masome complex may lead to release of the cytokines IL-1beta
and IL-18 and cell death. Reactive oxygen species (ROS) have
been proposed to be an upstream inducer of this complex and
the anti-oxidant N-Acetylcysteine amide (NACA) may provide
organ protection after hypoxia.

Objectives To map inflammasome activation in specific brain
regions of the pig after neonatal hypoxia-reoxygenation and to
investigate if the expression of different proteins in this pathway
are modulated by NACA.

Methods Study design (Table 1).

ELISA was used to measure IL-1b protein in cerebral cortex
and Realtime PCR for mRNA expression of NLRP3, ASC, IL-1b
and IL18 in cortex, cerebellum, hippocampus and striatum.

Results After severe hypoxia the protein expression of IL-1b in
cerebral cortex was reduced for the NACA treated pigs vs. sal-
in, p < 0.05.

Abstract PS-336 Table 2 Fold change for NLRP3, ASC, IL-18
and IL-1b measured in cerebral cortex. Significant difference in Fold
Change of ASC (*), p < 0.05. All values are Median values

Abstract PS-336 Table 1 Study design: Fifty-four newborn
piglets, age 12–36h, were included. Invasive blood pressure, EEG
and ECG were measured continuously. One control group (n = 6)
and 4 experimental groups (n = 12), exposed to global hypoxia,
until BE was either -15 or -20 mmol/l (moderate/severe asphyxia
or without NACA) The pigs were observed for 9.5 h

Reox. with air. 9.5 hours
