O-024 OUTCOME RESEARCH IN 77 PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION RECEIVING SILDENAFIL: A DOUBLE-BLIND, RANDOMISED CONTROLLED STUDY

1. Patel, E. Vataman, N. Revenco, L. Manic, H. Vataman, O. Repin. 1Paediatric Cardiology, Institute of Mother and Child, Chisinau, Moldova; 2Laboratory of Heart Failure, Institute of Cardiology, Chisinau, Moldova; 3Department of Paediatric SUMF, SUMP Nicolae Testemitanu, Chisinau, Moldova; 4Congenital Heart Diseases, Cardiac Surgery Centre, Chisinau, Moldova; 5Department of Echocardiography, Diagnostic German Centre, Chisinau, Moldova

Purpose PAH resulting from CHD – a major cause of postoperative morbidity and death. Sildenafil: selective inhibitor of phosphodiesterase-5 - an effective and promising pulmonary vasodilator, with minors reverse effects.

Methods This monocentric, randomised placebo-controlled study evaluated the efficacy, safety, tolerability of oral Sildenafil in children with severe PAH secondary congenital shunts (simple (14 patients), mixed (35), complex (28)). 77 PAH patients (35 – repaired shunts, 31 – palliative, 11 inoperable) assigned to placebo or Sildenafil – dose of 1–2 mg/kg/day each 8h: 6–12 months. Sildenafil group - 38 (mean age 19, 9 ± 5, 3 months: 16 boys/22 girls); placebo – 39 (mean age 21, 7 ± 7, 8 months: 22 boys/17 girls). Research protocol: FC NYHA; 0,001); O2 saturation (+3,1 ± 0,5%) but placebo (+0,6 ± 0,3%), (p < 0,05). No death in the Sildenafil group, but 5 in placebo.

Results Sildenafil patients improved FC from 3,16 ± 0,1 to 1,5 ± 0,1 (p < 0,001); effort tolerance (+152,5 ± 17,4m – 6 months and +184,3 ± 21,2 m - 12 months of treatment), (p < 0,001); O2 saturation (+3,1 ± 0,5%) but placebo (+0,6 ± 0,3%), (p < 0,001); PAPm decreased: 22,0 ± 2,2 at 6 months with 19,03 ± 2,3 mmHg - 12 months (p < 0,001); PVRI diminished from 6,4 ± 0,1 to 5,7 ± 0,3 UW/m2 (p < 0,05). No death in the Sildenafil group, but 5 in placebo.

Conclusions Sildenafil – efficient in treating severe PAH secondary to congenital shunts, but even more effective in children after cardiac surgery. Sildenafil improves FC, effort tolerability, O2 saturation, RV global function, diminishing PAPm and PVRI compared with placebo. Sildenafil has good safety, tolerability, favourable impact on life quality – insignificant adverse reactions.

O-025 DO SUSTAINED LUNG INFLATIONS DURING RESUSCITATION OF PRETERM INFANTS AFFECT CEREBRAL BLOOD VOLUME AND CEREBRAL REGIONAL OXYGEN SATURATION?

B. Schwaberger, G. Pichler, C. Binder, N. Baik, B. Urlesberger. Division of Neonatology, Medical University of Graz, Graz, Austria

10.1136/archdischild-2014-307384.94

Background and aim Sustained lung inflations (SLI) promote lung aeration and alveolar recruitment.

Changes in total haemoglobin (ΔHb) and cerebral tissue oxygenation index (cTOI) measured by near-infrared spectroscopy (NIRS) give information on changes in cerebral blood volume (CBV) and regional oxygen saturation, respectively.

Do SLI during resuscitation affect CBV and cTOI?

Methods Preterm infants ≥28+0 and <34+0 gestational weeks and need for respiratory support (RS) during postnatal transition were included. Within the first 15 min of life of each subject ΔHb and cTOI were continuously detected by using ‘NIRO-200-NX’ (Hamamatsu Japan).

Two groups were compared based on RS: SLI group: RS was started by applying 1–2– SLI for 15sec at 25 cmH2O and continued by continuous positive airway pressure (CPAP) or positive pressure ventilation (PPV).

Control group: CPAP/PPV depending on respiratory insufficiency.

Results 40 preterm infants (23 female) with mean gestational age of 32+1 weeks (±3 days) and mean birth weight of 1707 g (±470) were included. Demographic data did not show significant differences between groups.

Median ΔHb was in SLI/control group -0.38/0.20 µM 30 sec after initialising RS, -1.33/-0.43 µM after 60 sec, 3.37/2.30 µM after 2 min, -0.19/-0.46 µM after 3 min, 2.52/1.05 µM after 5min and 2.93/4.78 µM after 10 min.

Median cTOI increased in SLI/control group from 49/47% 30 sec after initialising RS to 54/50% after 60 sec, to 56/51% after 2 min, to 56/58% after 3 min, to 61/61% after 5 min, and to 65/69% after 10 min.

Conclusion Initialisation RS immediately after birth by using SLI in preterm infants did not show significant differences in CBV and cTOI compared to control group.

O-026 INFLUENCE OF PATENT FORAMEN OVALE (PFO) ON REGIONAL CEREBRAL OXYGEN SATURATION DURING IMMEDIATE NEONATAL TRANSITION

N. Baik, B. Urlesberger, T. Freid, B. Schwaberger, C. Binder, G. Pichler. Neonatology, Medical University Graz, Graz, Austria

10.1136/archdischild-2014-307384.95

Background During postnatal transition there is a significant association between regional cerebral oxygen saturation of the brain and the shunt via the ductus arteriosus (DA). The influence of the patent foramen ovale (PFO) on the cerebral regional saturation remains as a question.

Aim The aim of the study was to investigate the influence of the PFO on the cerebral oxygen saturation, measured by near-infrared spectroscopy (NIRS) after 15 min of neonatal transition.

Methods Observational study. Term neonates (>37 weeks of gestational age) after elective caesarian section and without any

Cerebral Oxygenation

Purpose

1. Plasma biomarker analysis is feasible in infants (35+ weeks of gestational age) after elective caesarian section and without any
