Background and aim Timely and accurate diagnosis of children with osteomyelitis is crucial, diagnostic imaging play a major role in determine the presence of acute osteomyelitis, treatment planning and follow up. Physicians encouraged to take the advantage of all available modalities as early intervention would prevent all possible adverse outcome of late diagnosis. The aim of this study is to explore the different imaging modalities in verifying the diagnosis of paediatrics acute osteomyelitis.

Methods All cases diagnosed with Acute Osteomyelitis between January 2000 and December 2013 were retrospectively reviewed at main tertiary children hospital. Our approach included a detailed description of radiological features of paediatric patients with acute haematogenous osteomyelitis.

Results 79 cases of acute osteomyelitis were diagnosed. 68 (86.1%) of children had X-Ray within first two weeks. (51.5%) reported as normal compared to (48.5%) abnormal (Periosteal reaction- Ostelytic lesions- soft tissue swelling). Ultrasound done in 34 (43%) of children, (70.6%) reported normal vs. (29.4%) abnormal (effusion). MRI study done in 73 (92.4%) and revealed osteomyelitis in 100% of imaging.16 patients (20.3%) had Bone Scan,(12.5%) reported normal compared to (87.5%) abnormal. (100%) of children with positive bone scan had similar osteomyelitis on MRI.

Conclusion Our study confirmed that MRI is the gold standard of imaging modality which combines high sensitivity with specificity to confirm osteomyelitis in children despite having normal X-ray, Ultrasound and Bone scan. Simple X-ray might be useful to diagnose osteomyelitis if MRI is difficult to perform or if the cost plays a major role in the patient care.

**Abstract PO-0241 Figure 1** Magnetic resonance imaging (MRI) of the brain showing bilateral thalamic infarction

**BILATERAL BASAL GANGLIA INFARCTION IN PNEUMOCOCCAL MENINGOECEPHALITIS IN A CHILD**

C. Neelkanth, R. Eijk. Intensive Care, Radboud University Medical Centre, Nijmegen, Netherlands

10.1136/archdischild-2014-307384.892

Background and aims Basal ganglia infarction is considered a complication of chronic refractory meningitis. In acute infection the basal ganglia are usually spared. Here we report an exceptional case of bilateral infarction of the basal ganglia in a child with acute S. pneumoniae meningoencephalitis.

Methods A 4 year old girl with a short history of fever and left sided otalgia presented with drowsiness in a referral hospital. Cerebral spinal fluid (CSF) examination showed pleocytosis (900 leucocytes/mm3) and immediately corticosteroids, ceftriaxone and acyclovir were started. Because of a rapid decline in consciousness she was transferred to our tertiary PICU centre.

Results Ad admission the girl had become unresponsive and was intubated. Her pupils were mid wide and non-reacting to light. Neurologic examination showed a bipyramidal syndrome with hypertonicity of the lower extremities, brisk deep tendon reflexes and bilateral positive Babinski’s. S.pneumoniae was cultured from CSF and blood. An MRI 4 days after admission showed bilateral sharply demarcated areas of high-signal intensity in the thalamus indicating infarction (Figure 1). In addition osteomyelitis of the tip of the petrous pyramid was observed. Her consciousness gradually improved with bilateral reactive pupils and spontaneous limb movements. Brainstem evoked response audiometry (BERA) of the left ear was negative. Gross motor deficits and impaired eye movements persisted.

Conclusion Acute pneumococcal meningoencephalitis can cause bilateral basal ganglia infarction in a child.

**PREVALENCE OF CONGENITAL TOXOPLASMOSIS IN NEWBORNS IN 2 EDUCATIONAL HOSPITALS IN TEHRAN IRAN**

S. Noorbakhsh, M. Kalani, Ali Ali Akbari. Research Center of Ped Infec Disease, Iran University of Medical Sciences, Tehran, Iran

10.1136/archdischild-2014-307384.893

Background and objective Frequency and clinical manifestations of congenital toxoplasmosis in Iran is not determined, object of study was to determine the Frequency of positive serologic neonates for Toxoplasma from birth and follow up of them.

Methods In a cohort prospective study (2011-2012), Cord blood sample obtained from 270 neonates, toxoplasma serology tests (IgG, IgM) done, cases with positive toxo-IgM treated and followed

Finding Positive IgM and IgG determined 1.5%, 44.1% respectively. The most common manifestation was Eye (50%) and brain (50%).

Conclusion Early treatment of infected neonates and wide variation of toxoplasma infection in country is so important. Adding the toxoplasma serologic tests to neonatal screening test is needed and recommended.

**PROCALCITONIN USE IN DIAGNOSIS OF PAEDIATRIC MENINGITIS**

S. Noorbakhsh, KH Shabanzadeh. Research Center of Ped Infec Disease, Iran University of Medical Sciences, Tehran, Iran

10.1136/archdischild-2014-307384.894

Background and aim Timely and accurate diagnosis of meningitis is crucial. This can be achieved through clinical evaluation and diagnostic laboratory test. In the last decade, Procalcitonin as a biomarker in acute infections has been used in the diagnosis of meningitis. The aim of this study was to investigate the use of Procalcitonin in the diagnosis of paediatric meningitis.

Methods Case series of 100 patients with documented diagnosis of meningitis. Procalcitonin was measured in samples of CSF on admission of children and at follow up.

Results Procalcitonin on admission of children was normal (0.5 ng/ml) in 50 (50%) vs. 50 (50%) abnormal. The diagnostic performance of Procalcitonin in meningitis was moderate. The area under the ROC curve was 0.72 (95% CI 0.61-0.82).

Conclusion Procalcitonin is useful in the diagnosis and follow up of children with meningitis.
